4100 National Parks Hwy.  
Carlsbad, NM 88220

## INTRODUCTION

The primary purpose of MgO in WIPP is "to decrease the solubilities of the actinide elements in transuranic (TRU) waste in any brine present in the repository after closure. ... In this report, 'MgO' refers to the bulk, granular material being emplaced in the WIPP to serve as the engineered barrier. MgO comprises periclase (pure, crystalline MgO - the main, reactive constituent of the WIPP engineered barrier) and various impurities. Pure, crystalline MgO is always referred to as periclase in this document. ... MgO will decrease actinide solubilities by consuming essentially all carbon dioxide (CO<sub>2</sub>) that would be produced by microbial consumption of all cellulosic, plastic, and rubber (CPR) materials in TRU waste, ... waste containers [and emplacement materials] in the repository. ... Consumption of CO<sub>2</sub> will prevent the acidification of brine or the production of significant quantities of carbonate ion (CO<sub>3</sub><sup>2-</sup>), which could increase actinide solubilities. Another function that MgO will perform in the repository is to consume water (H<sub>2</sub>O) in brine, or H<sub>2</sub>O vapor in the gaseous phase. ... After the WIPP is filled and sealed, periclase will react with H<sub>2</sub>O in the gaseous phase to form brucite (Mg(OH<sub>2</sub>)), or with H<sub>2</sub>O in brine to form brucite or amorphous or crystalline Mg-Cl-OH-H<sub>2</sub>O-bearing solids such as Mg<sub>3</sub>Cl(OH)<sub>5</sub>·4H<sub>2</sub>O or Mg<sub>2</sub>Cl(OH)<sub>3</sub>·4H<sub>2</sub>O. Periclase, brucite, and the Mg-Cl-OH-H<sub>2</sub>O phases will react with aqueous or gaseous CO<sub>2</sub> to form solids such as hydromagnesite (Mg<sub>5</sub>(CO<sub>3</sub>)<sub>4</sub>(OH)<sub>2</sub>·4H<sub>2</sub>O)" (U.S. DOE, 2004, Appendix BARRIERS).

Sandia National Laboratories – Carlsbad Program Group was requested by the DOE/CBFO to evaluate several samples from Martin Marietta Magnesia Specialties LLC (referred to as "Martin Marietta" hereafter) for possible use as the WIPP engineered barrier. If selected, Martin Marietta would replace Premier Chemicals, the current supplier of MgO. We are carrying out this evaluation by performing accelerated hydration tests, and are comparing the amount of brucite formed from the Martin Marietta samples to results obtained from similar tests with Premier MgO in 2001. This report presents the preliminary results of this work. We are also optimizing the parameters used to obtain accurate and meaningful hydration results. This work is carried out under the test plan of Snider et al. (2004), and the results are contained in the notebooks WIPP-MgO-CBD-19 and WIPP-MgO-CBD-20.

DPRP1:NF:11271051 of 35

RH

WIPP:1.4.2.5:TD:QA-L:Engineered Barrier

Information Only

It is assumed that the quantity of the reactive constituent (periclase) that reacts with aqueous H<sub>2</sub>O in these accelerated experiments is identical to that which will react with aqueous or gaseous CO<sub>2</sub> in the WIPP. Therefore, this experimental work quantifies the extent to which the MgO engineered barrier will consume CO<sub>2</sub>, which is in turn used (along with other information) to calculate MgO safety factors.

It should be noted that this work is not a test of the specifications required by WTS (2003). These requirements are:

1. "The sum of magnesium oxide (MgO) plus calcium oxide (CaO) shall be a minimum of 95%, with MgO being no less than 90%. The remainder of the material shall not contain any items considered hazardous to people or the environment.
2. Backfill material shall be of a dry granular form, which shall contain less than 0.5% particles which would be retained on a Tyler 3/8 inch sieve (3/8" × down).
3. Backfill material shall be test for reactivity as outlined in Attachment B, and shall meet the temperature rise listed in the test procedure.
4. The backfill material shall have a minimum loose bulk density of 87 lb/ft<sup>3</sup>."

Also, this work does not include any long-term testing (at either high or room temperatures) necessary to develop a kinetic model to predict the carbonation of this MgO. Finally, this work does not include characterization of the Martin Marietta MgO samples to the same extent as was previously done for Premier MgO, which involved X-ray-diffraction analysis and analysis of samples by scanning electron microscopy.

## MATERIALS

We received four samples of Martin Marietta MgO on August 27, 2004. Two of the samples did not meet the required density of 87 lb/ft<sup>3</sup> specified by WTS (2003); we did not carry out any experiments with these samples. The two other MgO samples, MagChem 10 WTS-30 (referred to as "WTS-30" hereafter) and MagChem 10 WTS-20 (WTS-20), did meet all the WTS specifications. We received another MgO sample from Martin Marietta: MagChem 10 WTS-60 (WTS-60) on September 24, 2004, which meets all WTS specifications, but shows a "marginal 87 lb/ft<sup>3</sup> density."

As specified by Martin Marietta, WTS-30, WTS-20, and WTS-60 are hard-burned magnesium oxide containing a minimum of 97% MgO. Sixty to 90% of WTS-30 passes through a U.S. 60 mesh screen sieve, while only 40% of WTS-20 passes through the same sieve. WTS-60 presents even larger size grains than WTS-30 and WTS-20; 95% to 90% pass through 6M mesh sieve, 50% to 80% pass through 16M mesh sieve, 15% to 40% pass through 30M sieve, and 15% to 30% pass through 100M mesh sieve screen. Therefore, the sizes of the three Martin Marietta MgO samples follow the order: WTS-30 < WTS-20 < WTS-60. As a result, the grain size of WTS-30 and WTS-20 could present a higher respiratory hazard for workers than WTS-60.

## METHODS

We perform accelerated hydration experiments to compare the amount of brucite formed from the three samples, WTS-30, WTS-20, and WTS-60. Similar experiments had been conducted in the study of Premier MgO.

The accelerated hydration test is performed as follows:

1. Place 5 g of MgO, weighed with a calibrated balance, in a high-density polyethylene or 125-mL polypropylene bottle.
2. Add 100 mL deionized (DI) water.
3. Place bottles in a 90 °C oven. Record the day and time at which the bottles are placed in the oven.
4. Shake the bottle three times a day for the first 10 days; after that, shake the bottles only once a day.
5. At a predetermined and recorded day and time, remove a bottle from the oven.
6. Immediately filter the content of the bottle through a Whatman ashless filter paper #41. Discard the liquid and keep the solid in a labeled container in a dessicator.
7. When the solid is dried, crush it with a mortar and pestle to obtain a fine powder. The powder is kept in the dessicator until loss on ignition (LOI) analysis.
8. The solid is tested by LOI, which is performed as follows:
  - A. Weigh a crucible on a calibrated balance.
  - B. Add about 2 g of MgO powder to be analyzed to the weighed crucible, weigh the crucible containing the MgO.
  - C. Place the crucible and its contents in a 60 °C furnace for 2 hours. This step is intended to remove the loosely bound water molecules, which are not participating in the formation of brucite.
  - D. Let the crucible and its contents cool down in a dessicator.
  - E. Weigh the cooled crucible with its contents.
  - F. Place in a 500 °C (or 750 °C) furnace for 3 hours. This step is intended to convert brucite to periclase.
  - G. Let the crucible and its contents cool down in a dessicator.
  - H. Weigh the cooled crucible with its contents.

The amount of brucite formed at the end of the test is calculated from the loss of water after the sample is dried at 60 °C and heated at 500 °C (or 750 °C).

The LOI-test parameters are also being evaluated. This test follows Steps 1 to 7 of the previous procedure. The last step is a modified version of Step 8 of the previous procedure:

1. Weigh a crucible on a calibrated balance.
2. Add about 2 g of MgO powder to be analyzed to the weighed crucible, weigh the crucible and the MgO.
3. Place the crucible and its contents in the furnace, set at a predetermined temperature,  $T_1$ , for a recorded period of time.
4. Let the crucible and its contents cool down in a dessicator.
5. Weigh the cooled crucible and its contents, and record the mass  $m_1$ .

6. Place the crucible and its contents in the furnace, set at the same temperature  $T_1$  as previously used, for a recorded period of time.
7. Let the crucible and its contents cool down in a dessicator.
8. Weigh the cooled crucible with its contents; record the mass as  $m_2$ .
  - A. If  $m_1 - m_2 < 0.0005$  g, place the crucible and its contents in the furnace, set at a predetermined temperature,  $T_2$  (where  $T_2 > T_1$ ), for a recorded period of time.
  - B. If  $m_1 - m_2 > 0.0005$  g, place the crucible and its contents in the furnace, set at the same temperature,  $T_1$ , for a recorded period of time.
9. Repeat 1. to 8. until data are obtained for a temperature of 800 °C.

## RESULTS AND DISCUSSION

Figures 1 through 3 present the amount of brucite formed, expressed as weight percent (wt %) of generated brucite, as a function of time, calculated from the results obtained after the LOI tests at 500 °C, for WTS-30, WTS-20, and WTS-60. The results obtained by A.C. Snider in 2001 for the test performed on Premier MgO are also included in each figure. On these figures, the different shades of diamond symbols indicate different batch experiments, which show the excellent reproducibility of the experimental results. The data presented in Figures 1 through 3 are also presented in Appendix Tables A1 through A3. These tables present the period of time each MgO sample was allowed to equilibrate with DI-water (age), the weight of the crucible and of the crucible containing the reacted MgO, both before and after heating at 60 °C or 500 °C, and the calculated wt % and mole percent (mol %) of brucite formed. The wt % of generated brucite is calculated from the LOI results, assuming that all the water consumed by the MgO during the hydration experiment converts exclusively to brucite. The mol % of brucite formed is calculated from the LOI results, assuming that all the water consumed by the MgO material during the hydration experiment converts exclusively to brucite and that the original MgO is exclusively periclase (pure crystalline MgO).

Figure 4 shows the superposition of the results (wt % of generated brucite) for WTS-30, WTS-20, WTS-60, and Premier MgO.

Finally, Figure 5 presents the amount of brucite formed as a function of time, calculated from the results obtained after LOI tests at 750 °C, for WTS-30; Figure 5 shows the results obtained by Snider and Xiong (2004) for Premier MgO after a similar LOI test. The data used to generate Figure 5 are presented in Table A1; the column labels are as described above. We also attempted to perform LOI tests at 750 °C for WTS-20, but no useful results could be obtained from these analyses, because of the tendency of this material to decrepitate when heated at such a high temperature. We have not attempted to run any LOI tests at 750 °C for WTS-60 to date, because we expect that we will have the same problem for WTS-60 at 750 °C as we have for WTS-20. Figures 1, 2, and 5 present the amount of brucite (wt %) in the unreacted materials (i.e., for the materials prior to any contact with water).

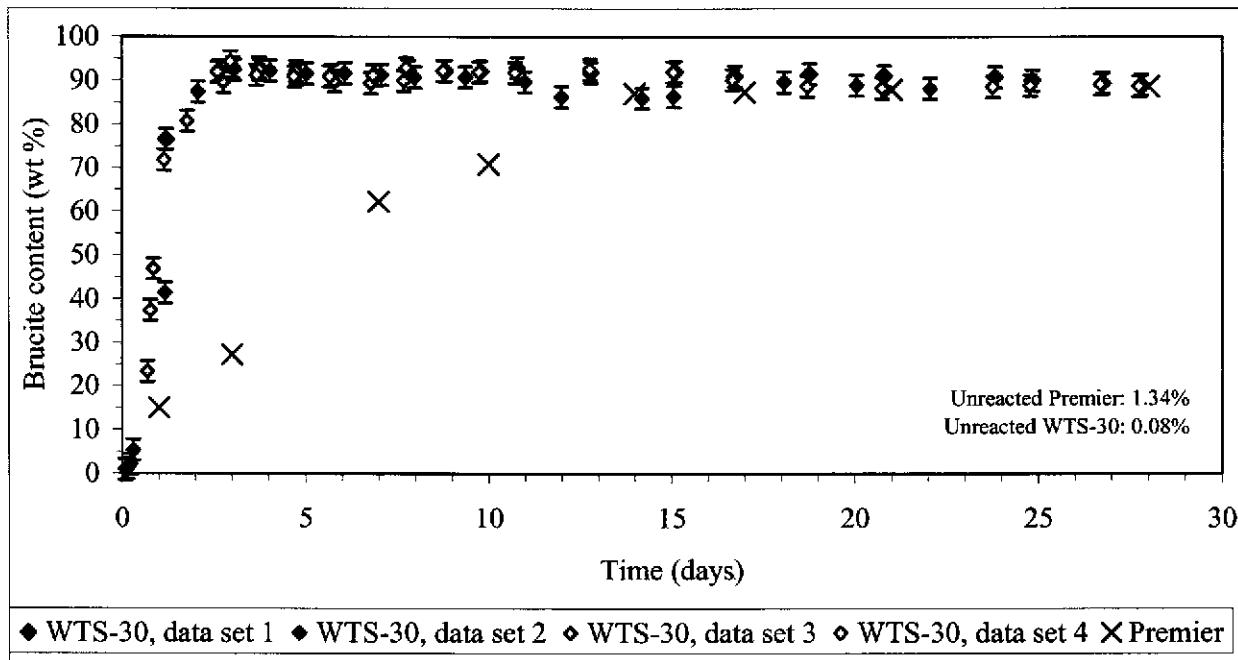

Figure 1. Comparison of the hydration of WTS-30 and Premier MgO in DI water at 90 °C. LOI at 500 °C.

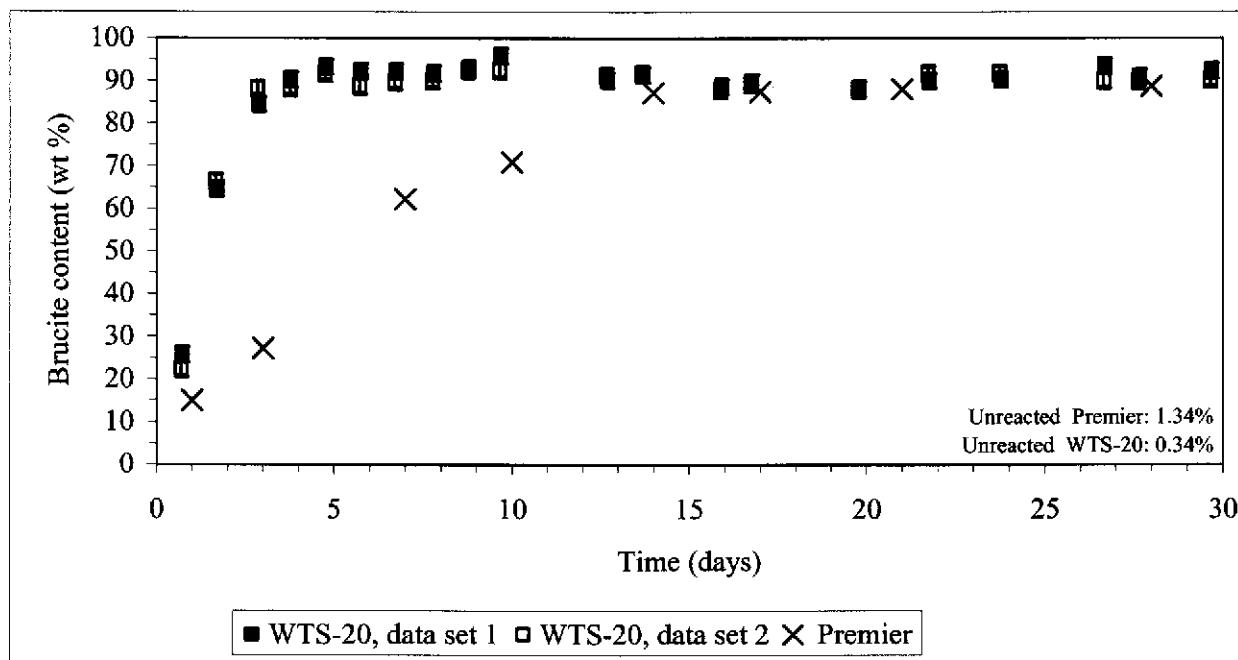

Figure 2. Comparison of the hydration of WTS-20 and Premier MgO in DI water at 90 °C. LOI at 500 °C.

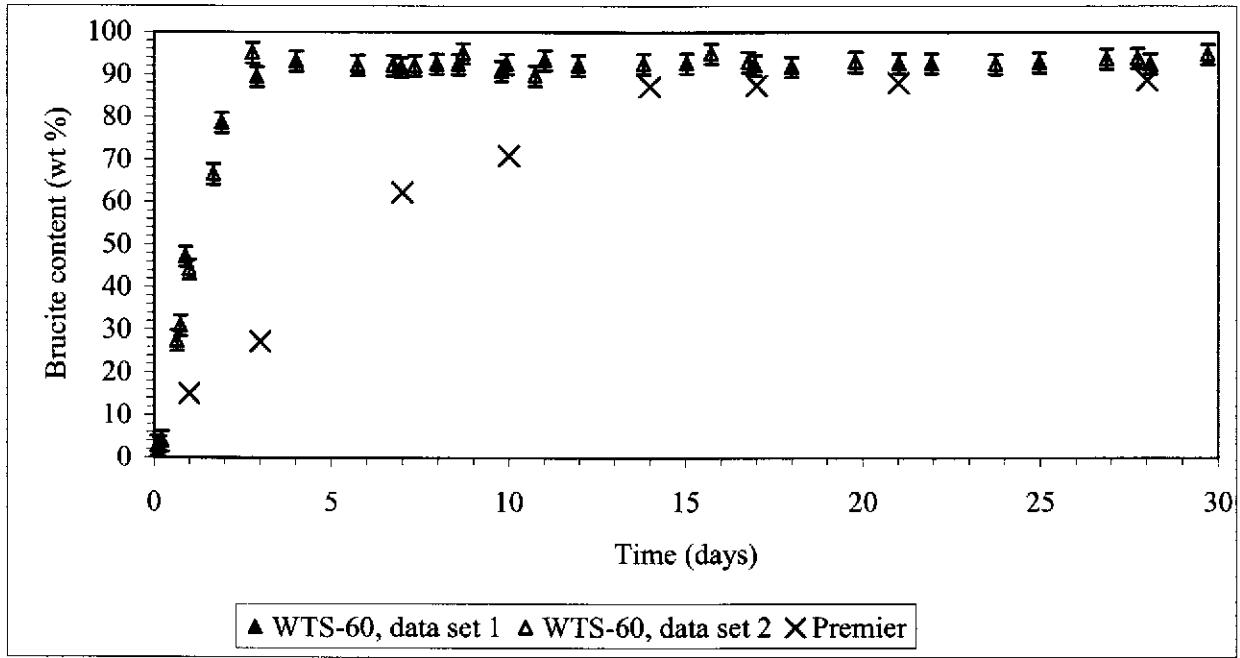

Figure 3. Comparison of the hydration of WTS-60 and Premier MgO in DI water at 90 °C. LOI at 500 °C.

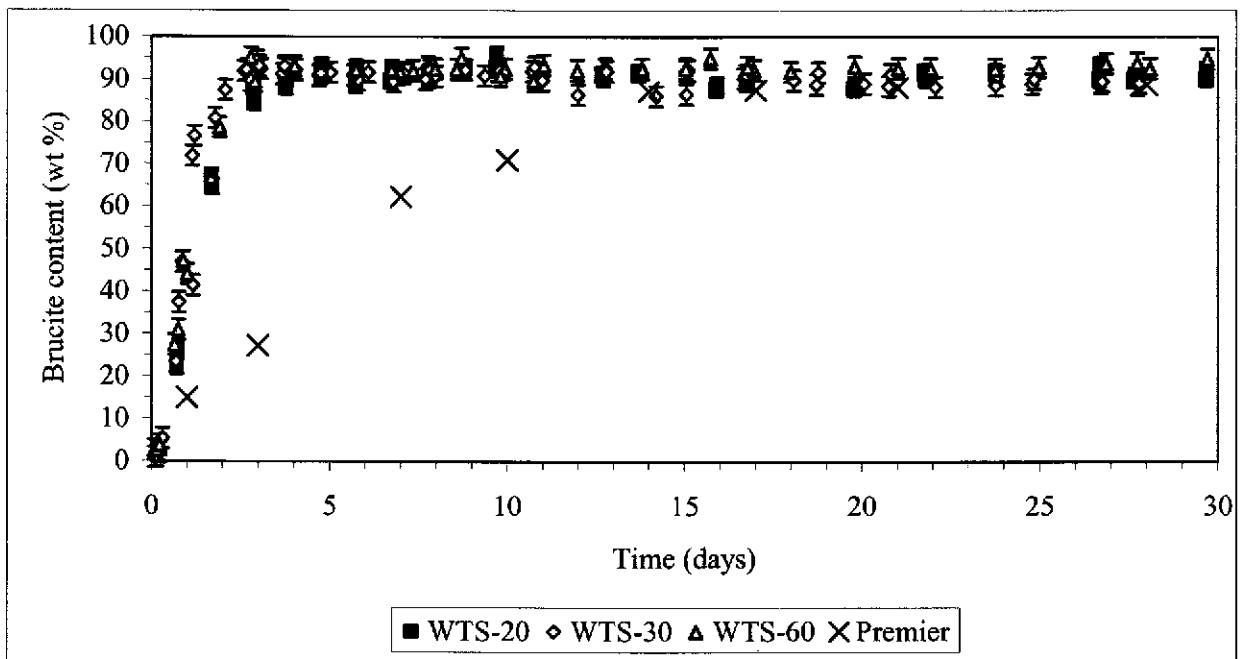

Figure 4. Comparison of the hydration of WTS-30, WTS-20, WTS-60, and Premier MgO in DI water at 90 °C. LOI at 500 °C.

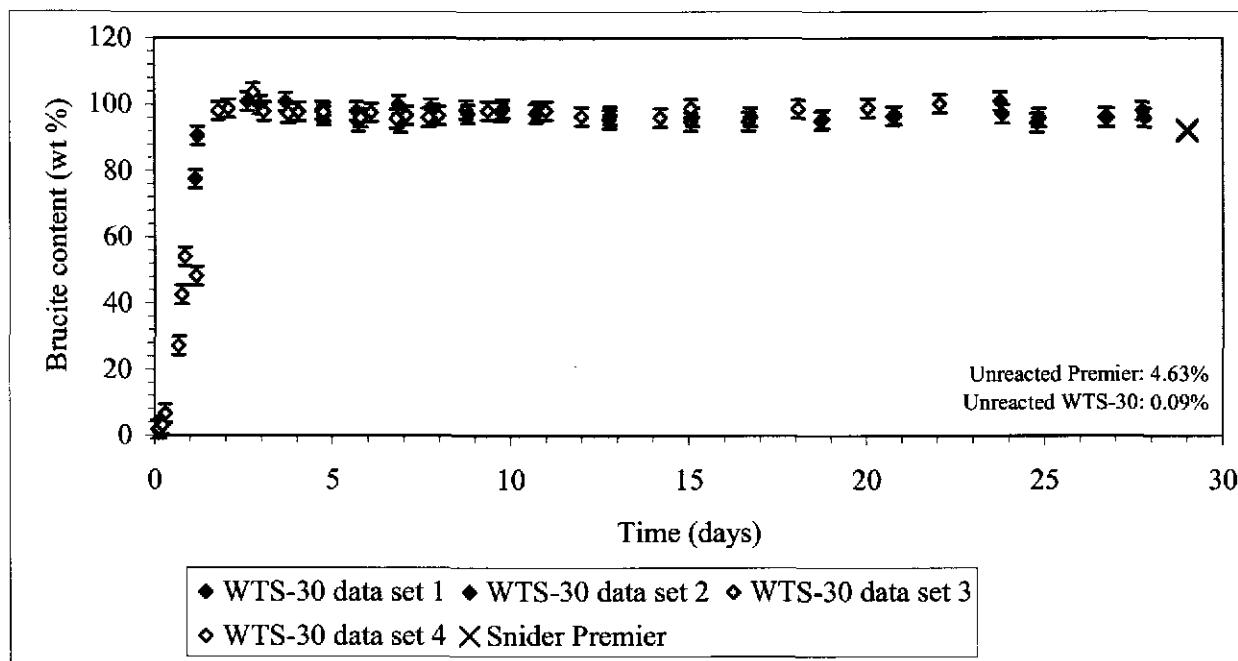

Figure 5. Comparison of the hydration of WTS-30 and Premier MgO in DI water at 90 °C. LOI at 750 °C.

Table 1 presents the average maximum wt and mol percents of brucite generated from each MgO sample (Premier MgO or Martin Marietta MgO), based on the LOI tests performed at 500 °C or 750 °C.

Table 1: Summary of Reactivity Data (mol% or wt % brucite produced from periclase)

LOI Temperature: Unit:	500 °C		750 °C	
	Mol %	Wt %	Mol %	Wt %
Premier MgO <sup>(1)</sup>	84.6	88.8	89	92
WTS-30 <sup>(2)</sup>	87 +/- 5	91 +/- 4	96 +/- 5	97 +/- 3
WTS-20 <sup>(2)</sup>	87 +/- 5	91 +/- 4	-	-
WTS-60 <sup>(2)</sup>	90 +/- 3	93 +/- 2	-	-

(1): From U.S. DOE (2004, Appendix BARRIERS) and Snider and Xiong (2004).

(2): This work.

Figures 1 through 4 and Table 1 show that the three Martin Marietta MgO samples hydrate similarly when subjected to the accelerated hydration test: the average wt % of brucite formed at equilibrium, based on the LOI test at 500 °C, from either WTS-30 or WTS-20 is  $91\% \pm 4$  ( $2\sigma$ ) and it is  $93\% \pm 2$  ( $2\sigma$ ) for WTS-60. All three Martin Marietta MgO samples react faster than Premier does. A maximum amount of brucite is generated from WTS-30, WTS-20, and WTS-60 after only 3 to 4 days, while the maximum amount of brucite generated from Premier MgO occurs after 15 days.

Figure 5 and Table 1 show that the LOI test at 750 °C yields higher calculated amounts of generated brucite than the results from an LOI at 500 °C. The average wt % of brucite formed at equilibrium from WTS-30 is  $97\% \pm 3$  ( $2\sigma$ ) based on the LOI test at 750 °C, while it is  $91\% \pm 4$  ( $2\sigma$ ) for tests run at 500 °C. This is also observed for Premier MgO: the average wt % of brucite formed at equilibrium from Premier, from LOI tests at 500 °C and 750 °C are 88.8% and 92%, respectively (Snider and Xiong, 2004). The data obtained for the unreacted MgO materials shows that the material left in the original container produces almost no brucite (i.e., periclase does not hydrate appreciably to brucite during storage).

In addition to the reactivity tests we perform, we are also optimizing the parameters used to obtain accurate and meaningful hydration results. A slight modification of the parameters might improve the LOI results; for example, a slow increase of temperature might avoid the decrepitation we observe for WTS-20 and WTS-60 at 750 °C. The experiments are currently being performed. In the current LOI test method, it is assumed that the samples should be dried for 2 hours at 60 °C to remove the loosely bound water molecules, which are not participating in the formation of brucite. Also, it is assumed that the samples brought to 500 °C for 3 hours, after the 60 °C drying step, should convert all the brucite to periclase. The present experiment is performed to (1) ensure that the period of time used to heat the samples at 60 °C and 500 °C is sufficient, (2) ensure that 60 °C is high enough to dry the sample, (3) ensure that 500 °C is appropriate to convert all and only brucite to periclase, (4) evaluate the type of minerals which decompose when heated for 3 hours at 750 °C, and (5) evaluate whether a gradual heating to 750 °C would prevent decrepitation of the material in the furnace.

The data are presented in Figure 6; they are plotted as the percent of mass lost between two measurements, after completion of drying at 60 °C. The experimental data are also presented in the Appendix, in Tables A4 to A6. Three replicates of each Martin Marietta MgO samples are being tested. The time necessary to obtain stable sample masses at 60 °C, 100 °C, 150 °C, and 200 °C are 2, 7, 2, and 6 hours, respectively. The tests at 300 °C have been performed for 45 hours and are still underway. The Martin Marietta sample WTS-30 has reached equilibrium and could be tested at a higher temperature, but the samples WTS-20 and WTS-60 have still not reached equilibrium for the 300 °C test after 45 hours. The data show that the rate at which a constant mass is obtained is a function of the grain size of the material; the larger the original grain size, the longer the sample must be heated. Similarly, the mass loss during the heating is a function of the original grain size; the larger the grain size, the more mass is lost in the furnace. The data also show that a 2 hour period is sufficient to obtain a constant mass for the 60 °C test. Moreover, additional calculations show identical results whether the percent of mass lost is calculated using the data obtained after the 60 °C, the 100 °C, or the

150 °C tests. Therefore, heating a sample at 60 °C for 2 hours is sufficient to remove the loosely bound water from the reacted MgO samples.

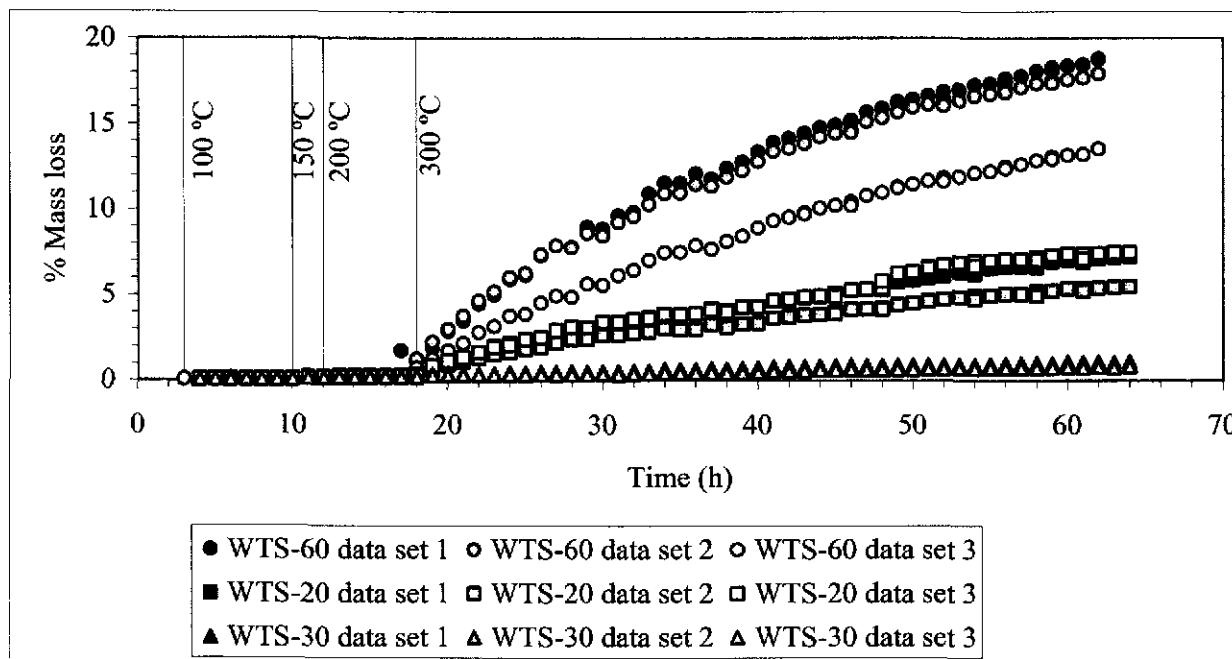

Figure 6. Mass loss of WTS-30, WTS-20, and WTS-60 hydrated in DI water at 90 °C. Samples dried at 60 °C for 2 hours.

## CONCLUSIONS

The preliminary results, presented in this report, show that the MgO materials supplied by Martin Marietta react faster than Premier MgO, and they produce slightly higher quantities of brucite (which will consume CO<sub>2</sub> in the WIPP) than Premier MgO does. The data from the 500 °C LOI test show that: (1) for WTS-30 and WTS-20, 87 ± 5 mol % and 91 ± 4 wt % brucite form; (2) for WTS-60, 90 ± 3 mol % and 93 ± 2 wt % brucite form; and (3) for Premier, 88.8 mol % and 94.6 wt % brucite form. Experiments with a LOI at 750 °C were performed for Premier MgO and WTS-30. The calculated results show larger amounts of generated brucite than for the 500 °C LOI tests and larger amounts of generated brucite for WTS-30 than for Premier MgO. The data from the 750 °C LOI showed that for WTS-30, 96 ± 5 mol % and 97 ± 3 wt % of brucite form; and for Premier, 89 mol % and 92 wt % brucite form. Although the 750 °C LOI could not be performed with WTS-20 and WTS-60, we expect results similar to those for WTS-30, based on the similarity of results obtained for the three Martin Marietta MgO samples for the 500 °C LOI tests. These preliminary results suggest that any of the three Martin Marietta MgO materials, WTS-30, WTS-20, and WTS-60, would be an acceptable to replace Premier MgO. The choice between any of the three Martin Marietta MgO materials can be based on other considerations, such as ES&H requirements.

However, additional data will be needed. The new MgO material will have to be tested to ensure it follows all the specifications required by WTS (2003). Long-term testing of the new MgO will be necessary, after it is selected, to develop a kinetic model to predict the carbonation of the new MgO material selected for the WIPP engineered barrier. Also, we must characterize the new MgO, to the same extent as was done for Premier MgO. Finally, the testing of LOI parameters needs to be completed to generate meaningful data for the calculation of the safety factor.
