APPENDIX SCR

The methodology used in the Waste Isolation Pilot Plant (WIPP) performance assessments for screening of features, events, and processes (FEPs) is presented in Section 6.2.2 of this application. This appendix presents the results of applying the screening methodology for the analyses that are required to evaluate compliance with the numerical performance requirements provided in Title 40 of the Code of Federal Regulations (CFR) Part 191. This appendix demonstrates comprehensiveness and assembles and organizes relevant decisions and assumptions concerning the phenomena modeled in performance assessments.

Section SCR.1 discusses natural FEPs that are potentially relevant to disposal system<sup>1</sup> performance. Section SCR.2 discusses waste- and repository-induced FEPs. Section SCR.3 discusses human-initiated events and processes (EPs). Key words placed in bold within the text represent FEPs being considered. Section SCR.4 maps retained FEPs into performance assessment codes. Attachment 1 discusses the compilation and construction of the FEP list used in this performance assessment.

**SCR.1 Natural FEPs**

The natural FEPs discussed in this section are potentially relevant to the analyses conducted to evaluate compliance with the Containment Requirements in 40 CFR § 191.13, the Individual Protection Requirements in 40 CFR § 191.15, and the Groundwater Protection Requirements in 40 CFR § 191.24. While natural FEPs are important to each of these provisions, assessments of compliance with 40 CFR § 191.15 and 40 CFR § 191.24 are based solely upon the undisturbed performance<sup>2</sup> of a disposal system and do not consider disruptions of the disposal system by unlikely natural events.

Unlikely natural events not accounted for in the undisturbed performance of the WIPP are those EPs that have not occurred in the past at a sufficient rate to affect the Salado Formation (hereafter referred to as the Salado) at the repository horizon within the controlled area, or to be expected to cause the release of radionuclides in the regulatory time frame. Further, the U.S. Department of Energy (DOE) believes that, for the WIPP, FEPs eliminated from the performance assessment calculations made to evaluate compliance with 40 CFR § 191.13 can

<sup>1</sup> Note that 40 CFR Part 191 defines the “disposal system” as any combination of engineered and natural barriers that isolates radioactive waste after disposal. Consistent with this definition, the DOE interprets the disposal system to be the repository (excavations, engineered aspects, disturbed rock zone [DRZ]) plus the controlled area, thus incorporating the natural barriers of the controlled area into the disposal system. The definition of the controlled area is provided in 40 CFR § 191.12 and is reproduced in Chapter 6.0.

<sup>2</sup> “Undisturbed performance” is defined in 40 CFR Part 191 to mean “the predicted behavior of a disposal system, including consideration of the uncertainties in predicted behavior, if the disposal system is not disrupted by human intrusion or the occurrence of unlikely natural events” (§ 191.12).

1 also be eliminated from the undisturbed performance assessment calculations made to  
2 evaluate compliance with 40 CFR § 191.15 and 40 CFR § 191.24.

3  
4 In the remainder of this section, the DOE discusses natural FEPs in the context of the FEP  
5 categorization scheme presented in Table SCR-1. The categories concerned with geology  
6 (Section SCR.1.1), subsurface hydrology (Section SCR.1.2), and geochemistry (Section  
7 SCR.1.3), relate to the subsurface structure, fluid flow, and fluid chemistry, respectively. The  
8 categories concerned with geomorphology (Section SCR.1.4), surface hydrology (Section  
9 SCR.1.5), climate (Section SCR.1.6), marine environment (Section SCR.1.7), and ecology  
10 (Section SCR.1.8), relate to the potential influence of natural FEPs on conditions at and near  
11 the ground surface. FEPs presented in Table SCR-1 are printed in bold in the text of the FEP  
12 screening discussions.

### 13 **SCR.1.1 Geological FEPs**

#### 14 **SCR.1.1.1 Stratigraphy**

15  
16  
17  
18 *The stratigraphy of the geological formations in the region of the WIPP is accounted for in*  
19 *performance assessment calculations. The presence of brine reservoirs in the Castile is*  
20 *accounted for in performance assessment calculations.*

21  
22 The **stratigraphy** and geology of the region around the WIPP, including the distribution and  
23 characteristics of pressurized **brine reservoirs** in the Castile Formation (hereafter referred to  
24 as the Castile), are discussed in detail in Section 2.1.3. The stratigraphy of the geological  
25 formations in the region of the WIPP is accounted for in performance assessment calculations  
26 through the setup of the model geometries (Section 6.4.2). The presence of brine reservoirs is  
27 accounted for in the treatment of inadvertent drilling (Sections 6.4.12.6 and 6.4.8).

#### 28 **SCR.1.1.2 Tectonics**

29  
30  
31 *The effects of regional tectonics, regional uplift and subsidence, and changes in regional*  
32 *stress have been eliminated from performance assessment calculations on the basis of low*  
33 *consequence to the performance of the disposal system.*

34  
35 **Regional tectonics** encompasses two related issues of concern: the overall level of regional  
36 stress and whether any significant **changes in regional stress** might occur.

37  
38 The tectonic setting and structural features of the area around the WIPP are described in  
39 Section 2.1.5. In summary, there is no geological evidence for Quaternary regional tectonics  
40 in the Delaware Basin. The eastward tilting of the region has been dated as mid-Miocene to  
41 Pliocene by King (1948, 120 – 121) and is associated with the uplift of the Guadalupe  
42 Mountains to the west. Fault zones along the eastern margin of the basin, where it flanks the  
43 Central Basin Platform, were active during the Late Permian. Evidence for this includes the  
44 displacement of the Rustler Formation (hereafter referred to as the Rustler) observed by Holt

Legend:

- UP FEPs accounted for in the assessment calculations for undisturbed performance for 40 CFR § 191.13 (as well as 40 CFR § 191.15 and Subpart C of 40 CFR Part 191).
- DP FEPs accounted for (in addition to all UP FEPs) in the assessment calculations for disturbed performance for 40 CFR § 191.13.
- SO-R FEPs eliminated from performance assessment calculations on the basis of regulations provided in 40 CFR Part 191 and criteria provided in 40 CFR Part 194.
- SO-C FEPs eliminated from performance assessment (and compliance assessment) calculations on the basis of consequence.
- SO-P FEPs eliminated from performance assessment (and compliance assessment) calculations on the basis of low probability of occurrence.

and Powers (1988, 4 – 14; see also Appendix FAC) and the thinning of the Dewey Lake Redbeds (hereafter referred to as the Dewey Lake) reported by Schiel (1994). There is, however, no surface displacement along the trend of these fault zones, indicating that there has been no significant Quaternary movement. Other faults identified within the evaporite sequence of the Delaware Basin are inferred by Barrows' figures in Borns et al. (1983, 58 – 60) to be the result of salt deformation rather than regional tectonic processes. According to Muehlberger et al. (1978, 338), the nearest faults on which Quaternary movement has been identified lie to the west of the Guadalupe Mountains and are of minor regional significance. The effects of regional tectonics and changes in regional stress have therefore been eliminated from performance assessment calculations on the basis of low consequence to the performance of the disposal system.

There are no reported stress measurements from the Delaware Basin, but a low level of regional stress has been inferred from the geological setting of the area (see Section 2.1.5). The inferred low level of regional stress and the lack of Quaternary tectonic activity indicate that regional tectonics and any changes in regional stress will be minor and therefore of low consequence to the performance of the disposal system. Even if rates of regional tectonic movement experienced over the past 10 million years continue, the extent of **regional uplift and subsidence** over the next 10,000 years would only be about several feet (approximately 1 meter). This amount of uplift or subsidence would not lead to a breach of the Salado because the salt would deform plastically to accommodate this slow rate of movement. Uniform regional uplift or a small increase in regional dip consistent with this past rate could give rise to downcutting by rivers and streams in the region. The extent of this downcutting would be little more than the extent of uplift, and reducing the overburden by 1 or 2 meters would have no significant effect on groundwater flow or contaminant transport in units above or below the Salado. Thus, the effects of regional uplift and subsidence have been eliminated

1 from performance assessment calculations on the basis of low consequence to the  
2 performance of the disposal system.

3  
4 SCR.1.1.3 Structural FEPs

5  
6 SCR.1.1.3.1 Deformation

7  
8 *Natural salt deformation and diapirism at the WIPP site over the next 10,000 years on a scale*  
9 *severe enough to significantly affect performance of the disposal system has been eliminated*  
10 *from performance assessment calculations on the basis of low probability of occurrence.*

11  
12 Deformed salt in the lower Salado and upper strata of the Castile has been encountered in a  
13 number of boreholes around the WIPP site; the extent of existing salt deformation is  
14 summarized in Section 2.1.6.1, and further detail is provided in Appendix DEF.

15  
16 A number of mechanisms may result in **salt deformation**: in massive salt deposits, buoyancy  
17 effects or **diapirism** may cause salt to rise through denser, overlying units; and in bedded salt  
18 with anhydrite or other interbeds, gravity foundering of the interbeds into the halite may take  
19 place. Results from rock mechanics modeling studies (see Appendix DEF) indicate that the  
20 time scale for the deformation process is such that significant natural deformation is unlikely  
21 to occur at the WIPP site over any time frame significant to waste isolation. Thus, natural  
22 salt deformation and diapirism severe enough to alter existing patterns of groundwater flow or  
23 the behavior of the disposal system over the regulatory period has been eliminated from  
24 performance assessment calculations on the basis of low probability of occurrence over the  
25 next 10,000 years.

26  
27 SCR.1.1.3.2 Fracture Development

28  
29 *Naturally induced changes in fracture properties that may affect groundwater flow or*  
30 *radionuclide transport in the region of the WIPP have been eliminated from performance*  
31 *assessment calculations on the basis of low consequence to the performance of the disposal*  
32 *system. The formation of fractures has been eliminated from performance assessment*  
33 *calculations on the basis of a low probability of occurrence over 10,000 years.*

34  
35 Groundwater flow in the region of the WIPP and transport of any released radionuclides may  
36 take place along fractures. The rate of flow and the extent of transport will be influenced by  
37 fracture characteristics such as orientation, aperture, asperity, fracture length and connectivity,  
38 and the nature of any linings or infills. These characteristics are accounted for in the  
39 performance assessment calculations through the description of the hydrogeological properties  
40 of the transmissive units (Sections 2.2.1 and 6.4.6.2).

41  
42 Dissolution and precipitation of minerals in fractures are discussed in Sections SCR.1.1.5.1  
43 and SCR.1.1.5.2, respectively. **Changes in fracture properties** could also arise through  
44 natural changes in the local stress field, for example, through erosion or sedimentation

1 changing the amount of overburden (see Sections SCR.1.4.3.2 and SCR.1.4.3.3). The extent  
2 of natural changes in stress is expected to be small, and naturally induced changes in fractures  
3 that may affect groundwater flow or radionuclide transport in the region of the WIPP,  
4 therefore, have been eliminated from performance assessment calculations on the basis of low  
5 consequence to the performance of the disposal system.

6  
7 The **formation of fractures** requires larger changes in stress than are required for changes to  
8 the properties of existing fractures to overcome the shear and tensile strength of the rock. The  
9 regional tectonic setting of the Delaware Basin is described in Section 2.1.5. It is concluded  
10 that no significant changes in regional stress are expected over the regulatory period (see also  
11 Section SCR.1.1.2). The formation of new fracture sets has therefore been eliminated from  
12 performance assessment calculations on the basis of a low probability of occurrence over  
13 10,000 years.

14  
15 Repository-induced fracturing of the DRZ and Salado interbeds is accounted for in  
16 performance assessment calculations, and is discussed in Section SCR.2.3.1.

17  
18 *SCR.1.1.3.3 Fault Movement*

19  
20 *The naturally induced formation of new faults and fault movement of sufficient magnitude to*  
21 *significantly affect the performance of the disposal system have been eliminated from*  
22 *performance assessment calculations on the basis of low probability of occurrence over*  
23 *10,000 years.*

24  
25 Faults are present in the Delaware Basin in both the units underlying the Salado and in the  
26 Permian evaporite sequence (see Section 2.1.5.2). According to Powers et al. (1978, 4 – 57,  
27 included as Appendix GCR), there is evidence that movement along faults within the pre-  
28 Permian units affected the thickness of Early Permian strata, but these faults did not exert a  
29 structural control on the deposition of the Castile, the Salado, or the Rustler. Fault zones  
30 along the margins of the Delaware Basin were active during the Late Permian Period. Along  
31 the eastern margin, where the Delaware Basin flanks the Central Basin Platform, Holt and  
32 Powers (Appendix FAC, 4 – 14) note that there is displacement of the Rustler, and Schiel  
33 (1994) notes that there is thinning of the Dewey Lake. There is, however, no surface  
34 displacement along the trend of these fault zones, indicating that there has been no significant  
35 Quaternary movement. Muehlberger et al. (1978, 338) note that the nearest faults on which  
36 Quaternary movement has been identified lie to the west of the Guadalupe Mountains.

37  
38 The absence of Quaternary fault scarps and the general tectonic setting and understanding of  
39 its evolution indicate that large-scale, tectonically-induced **fault movement** within the  
40 Delaware Basin can be eliminated from performance assessment calculations on the basis of  
41 low probability over 10,000 years. The stable tectonic setting also allows the **formation of**  
42 **new faults** within the basin over the next 10,000 years to be eliminated from performance  
43 assessment calculations on the basis of low probability of occurrence.

1 Subsidence above natural dissolution features could lead to the formation of, and movement  
2 along, local faults. However, significant dissolution in the region of the waste panels has been  
3 eliminated from performance assessment calculations on the basis of low probability of  
4 occurrence over 10,000 years (see Section SCR.1.1.5.1), so faults arising from dissolution  
5 have also been eliminated on the basis of low probability of occurrence.

6  
7 *SCR.1.1.3.4 Seismic Activity*

8  
9 *The postclosure effects of seismic activity on the repository and the DRZ are accounted for in*  
10 *performance assessment calculations.*

11  
12 This section is concerned with the effects of seismic activity away from the immediate source  
13 region, and only the effects of groundshaking and earthquakes are discussed. Other sections  
14 discuss the direct effects of fault movement (SCR.1.1.3.3), and changes in hydrogeology  
15 induced by seismic activity (SCR.1.2.2.5).

16  
17 *SCR.1.1.3.4.1 Causes of Seismic Activity*

18  
19 Seismic activity describes transient ground motion that may be generated by several energy  
20 sources. There are two possible causes of seismic activity that could potentially affect the  
21 WIPP site: natural and human induced. Natural seismic activity is caused by fault movement  
22 (earthquakes) when the buildup of strain in rock is released through sudden rupture or  
23 movement. Human-induced seismic activity may result from a variety of surface and  
24 subsurface activities, such as explosions, mining, fluid injection, and fluid withdrawal that are  
25 discussed in Section SCR.3.

26  
27 *SCR.1.1.3.4.2 Groundshaking*

28  
29 Ground vibration and the consequent shaking of buildings and other structures are the most  
30 obvious effects of seismic activity. Once the repository and shafts have been sealed, however,  
31 existing surface structures will be dismantled. Postclosure performance assessments are  
32 concerned with the effects of seismic activity on the closed repository.

33  
34 In regions of low and moderate seismic activity, such as the Delaware Basin, rocks behave  
35 elastically in response to the passage of seismic waves, and there are no long-term changes in  
36 rock properties, and the effects of earthquakes beyond the DRZ have been eliminated from  
37 performance assessment calculations on the basis of low consequence to the performance of  
38 the disposal system. An inelastic response, such as cracking, is only possible where there are  
39 free surfaces, as in the roof and walls of the repository prior to closure by creep. **Seismic**  
40 **activity** could, therefore, have an effect on the properties of the DRZ.

41  
42 An assessment of the extent of damage in underground excavations caused by groundshaking  
43 largely depends on observations from mines and tunnels. Because such excavations tend to  
44 take place in rock types more brittle than halite, these observations cannot be related directly

1 to the behavior of the WIPP. According to Wallner (1981, 244), the DRZ in brittle rock types  
2 is likely to be more highly fractured and hence more prone to spalling and rockfalls than an  
3 equivalent zone in salt. Relationships between groundshaking and subsequent damage  
4 observed in mines will therefore be conservative with respect to the extent of damage induced  
5 at the WIPP by seismic activity.

6  
7 Dowding and Rozen (1978) classified damage in underground structures following seismic  
8 activity and found that no damage (cracks, spalling, or rockfalls) occurred at accelerations  
9 below 0.2 gravities and that only minor damage occurred at accelerations up to 0.4 gravities.  
10 Lenhardt (1988, 392) showed that a magnitude 3 earthquake would have to be within 0.6 mile  
11 (1 kilometer) of a mine to result in falls of loose rock. The risk of seismic activity in the  
12 region of the WIPP reaching these thresholds is discussed below.

13  
14 *SCR.1.1.3.4.3 Seismic Risk in the Region of the WIPP*

15  
16 Prior to the introduction of a seismic monitoring network in 1960, most recorded earthquakes  
17 in New Mexico were associated with the Rio Grande Rift, although small earthquakes were  
18 detected in other parts of the region. In addition to continued activity in the Rio Grande Rift,  
19 the instrumental record has shown a significant amount of seismic activity originating from  
20 the Central Basin Platform and a number of small earthquakes in the Los Medaños area.  
21 Seismic activity in the Rio Grande Rift is associated with extensional tectonics in that area.  
22 Seismic activity in the Central Basin Platform may be associated with natural earthquakes, but  
23 there are also indications that this activity occurs in association with oil-field activities such as  
24 fluid injection. Small earthquakes in the Los Medaños region have not been precisely located,  
25 but may be the result of mining activity in the region. Section 2.6.2 contains additional  
26 discussion of seismic activity and risk in the WIPP region.

27  
28 The instrumental record was used as the basis of a seismic risk study primarily intended for  
29 design calculations of surface facilities rather than for postclosure performance assessments.  
30 The use of this study to define probable ground accelerations in the WIPP region over the next  
31 10,000 years is based on the assumptions that hydrocarbon extraction and potash mining will  
32 continue in the region and that the regional tectonic setting precludes major changes over the  
33 next 10,000 years.

34  
35 Three source regions were used in calculating seismic risk: the Rio Grande Rift, the Central  
36 Basin Platform, and part of the Delaware Basin province (including the Los Medaños). Using  
37 conservative assumptions about the maximum magnitude event in each zone, the study  
38 indicated a return period of about 10,000 years (annual probability of occurrence of  $10^{-4}$ ) for  
39 events producing ground accelerations of 0.1 gravities. Ground accelerations of 0.2 gravities  
40 would have an annual probability of occurrence of about  $5 \times 10^{-6}$ .

41  
42 The results of the seismic risk study and the observations of damage in mines due to  
43 groundshaking, give an estimated annual probability of occurrence of between  $10^{-6}$  and  $10^{-8}$   
44 for events that could increase the permeability of the DRZ. The DRZ is accounted for in

1 performance assessment calculations as a zone of permanently high permeability (see  
2 Section 6.4.5.3); this treatment is considered to account for the effects of any potential seismic  
3 activity.

4  
5 SCR.1.1.4 Crustal Processes

6  
7 SCR.1.1.4.1 Igneous Activity

8  
9 *Volcanic activity has been eliminated from performance assessment calculations on the basis  
10 of low probability of occurrence over 10,000 years. The effects of magmatic activity have  
11 been eliminated from the performance assessment calculations on the basis of low  
12 consequence to the performance of the disposal system.*

13  
14 SCR.1.1.4.1.1 Volcanic Activity

15  
16 The Paleozoic and younger stratigraphic sequences within the Delaware Basin are devoid of  
17 locally derived volcanic rocks. Volcanic ashes (dated at 13 million years and 0.6 million year)  
18 do occur in the Gatuña Formation (hereafter referred to as the Gatuña), but these are not  
19 locally derived. Within eastern New Mexico and northern, central, and western Texas, the  
20 closest Tertiary volcanic rocks with notable areal extent or tectonic significance to the WIPP  
21 are approximately 100 miles (160 kilometers) to the south in the Davis Mountains volcanic  
22 area. The closest Quaternary volcanic rocks are 150 miles (250 kilometers) to the northwest  
23 in the Sacramento Mountains. No volcanic rocks are exposed at the surface within the  
24 Delaware Basin.

25  
26 **Volcanic activity** is associated with particular tectonic settings: constructive and destructive  
27 plate margins, regions of intraplate rifting, and isolated hot-spots in intraplate regions. The  
28 tectonic setting of the WIPP site and the Delaware Basin is remote from plate margins, and  
29 the absence of past volcanic activity indicates the absence of a major hot spot in the region.  
30 Intraplate rifting has taken place along the Rio Grande some 120 miles (200 kilometers) west  
31 of the WIPP site during the Tertiary and Quaternary Periods. Igneous activity along this rift  
32 valley is comprised of sheet lavas intruded on by a host of small-to-large plugs, sills, and other  
33 intrusive bodies. However, the geological setting of the WIPP site within the large and stable  
34 Delaware Basin allows volcanic activity in the region of the WIPP repository to be eliminated  
35 from performance calculations on the basis of low probability of occurrence over the next  
36 10,000 years.

37  
38 SCR.1.1.4.1.2 Magmatic Activity

39  
40 **Magmatic activity** is defined as the subsurface intrusion of igneous rocks into country rock.  
41 Deep intrusive igneous rocks crystallize at depths of several kilometers and have no surface or  
42 near-surface expression until considerable erosion has taken place. Alternatively, intrusive  
43 rocks may form from magma that has risen to near the surface or in the vents that give rise to  
44 volcanoes and lava flows. Magma near the surface may be intruded along subvertical and

1 subhorizontal discontinuities (forming dikes and sills, respectively), and magma in volcanic  
2 vents may solidify as plugs. The formation of such features close to a repository or the  
3 existence of a recently intruded rock mass could impose thermal stresses inducing new  
4 fractures or altering the hydraulic characteristics of existing fractures.

5  
6 The principal area of magmatic activity in New Mexico is the Rio Grande Rift, where  
7 extensive intrusions occurred during the Tertiary and Quaternary Periods. The Rio Grande  
8 Rift, however, is in a different tectonic province than the Delaware Basin, and its magmatic  
9 activity is related to the extensional stress regime and high heat flow in that region.

10  
11 Within the Delaware Basin, there is a single identified outcrop of a lamprophyre dike about  
12 40 miles (70 kilometers) southwest of the WIPP (see Section 2.1.5.4 and Appendix GCR for  
13 more detail). Closer to the WIPP site, similar rocks have been exposed within potash mines  
14 some 10 miles (15 kilometers) to the northwest, and igneous rocks have been reported from  
15 petroleum exploration boreholes. Material from the subsurface exposures has been dated at  
16 around 35 million years. Some recrystallization of the host rocks took place alongside the  
17 intrusion, and there is evidence that minor fracture development and fluid migration also  
18 occurred along the margins of the intrusion. However, the fractures have been sealed, and  
19 there is no evidence that the dike acted as a conduit for continued fluid flow.

20  
21 Aeromagnetic surveys of the Delaware Basin have shown anomalies that lie on a linear  
22 southwest-northeast trend that coincides with the surface and subsurface exposures of  
23 magmatic rocks. There is a strong indication therefore of a dike or a closely related set of  
24 dikes extending for at least 70 miles (120 kilometers) across the region (see Section 2.1.5.4).  
25 The aeromagnetic survey conducted to delineate the dike showed a magnetic anomaly that is  
26 several miles (several kilometers) wide at depth and narrows to a thin trace near the surface.  
27 This pattern is interpreted as the result of an extensive dike swarm at depths of less than 2.5  
28 miles (approximately 4.0 kilometers) near the Precambrian basement, from which a limited  
29 number of dikes have extended towards the surface.

30  
31 Magmatic activity has taken place in the vicinity of the WIPP site in the past, but the igneous  
32 rocks have cooled over a long period. Any enhanced fracturing or conduits for fluid flow  
33 have been sealed by salt creep and mineralization. Continuing magmatic activity in the Rio  
34 Grande Rift is too remote from the WIPP location to be of consequence to the performance of  
35 the disposal system. Thus, the effects of magmatic activity have been eliminated from  
36 performance assessment calculations on the basis of low consequence to the performance of  
37 the disposal system.

38  
39 *SCR.1.1.4.2 Metamorphism*

40  
41 *Metamorphic activity has been eliminated from performance assessment calculations on the*  
42 *basis of low probability of occurrence over the next 10,000 years.*

1 **Metamorphic activity**, that is, solid state recrystallization changes to rock properties and  
2 geologic structures through the effects of heat and/or pressure, requires depths of burial much  
3 greater than the depth of the repository. Regional tectonics that would result in the burial of  
4 the repository to the depths at which the repository would be affected by metamorphic activity  
5 have been eliminated from performance assessment calculations on the basis of low  
6 probability of occurrence; therefore, metamorphic activity has also been eliminated from  
7 performance assessment calculations on the basis of low probability of occurrence over the  
8 next 10,000 years.

9  
10 **SCR.1.1.5 Geochemical FEPs**

11  
12 **SCR.1.1.5.1 Dissolution**

13  
14 *Shallow dissolution is accounted for in performance assessment calculations. Deep*  
15 *dissolution and the formation of associated features (for example, solution chimneys, breccia*  
16 *pipes, collapse breccias) at the WIPP site have been eliminated from performance assessment*  
17 *calculations on the basis of low probability of occurrence over the next 10,000 years. Lateral*  
18 *dissolution has been eliminated from performance assessment calculations on the basis of low*  
19 *consequence to the performance of the disposal system.*

20  
21 This section discusses a variety of styles of dissolution that have been active in the region of  
22 the WIPP or in the Delaware Basin. A distinction has been drawn between **shallow**  
23 **dissolution**, involving percolation of groundwater and mineral dissolution in the Rustler;  
24 **lateral dissolution**, involving dissolution at the top of the Salado; and **deep dissolution**  
25 taking place in the Castile and the base of the Salado. Dissolution will initially enhance  
26 porosities, but continued dissolution may lead to compaction of the affected units with a  
27 consequent reduction in porosity. Compaction may result in fracturing of overlying brittle  
28 units and increased permeability. Extensive dissolution may create cavities (karst) and result  
29 in the total collapse of overlying units. This topic is discussed further in Section 2.1.6.2.

30  
31 **SCR.1.1.5.1.1 Shallow Dissolution**

32  
33 Flow through fractures is an important contributor to groundwater flow in the Culebra and  
34 other units of the Rustler, and the conductivity of fractures is the principal control of this flow.  
35 East of the WIPP site, a significant proportion of the fractures within the Culebra are infilled  
36 with secondary gypsum (see Figure 2-12), whereas to the west of the site most fractures are  
37 open. This distribution of infilled fractures closely parallels the spatial variability of lateral  
38 transmissivity in the Culebra (Figure 2-30) and is accounted for in performance assessment  
39 calculations through the use of geostatistically conditioned transmissivity fields  
40 (Section 6.4.6.2).

41  
42 Groundwater basin modeling indicates that the Culebra becomes progressively more confined  
43 toward the east. This corresponds to an increase in the overburden towards the east and a  
44 decrease in the fracturing associated with dissolution at the Rustler - Salado boundary. The

1 analysis presented below indicates that the lateral extent of dissolution at the top of the Salado  
2 is not expected to reach the edge of the controlled area for some 225,000 years, and the rates  
3 of erosion in this region (see Section SCR.1.4.3.2) are very low. The pattern of vertical  
4 transmissivity in the Rustler is therefore not expected to change significantly during the next  
5 10,000 years, and neither the degree of confinement of the Culebra nor the pattern of open  
6 fractures in this unit will undergo significant change during this period.

7  
8 Percolating groundwater will result in some dissolution and precipitation of fracture infills  
9 over the next several climate cycles. The present pattern of secondary gypsum in fractures  
10 within the Culebra is considered to be the result of changes in precipitation and recharge over  
11 many climate cycles and a similar degree of spatial variability is anticipated to persist into the  
12 future. The pattern of secondary gypsum is not considered to be the result of progressive  
13 movement of a dissolution front across the area, and the extent of changes in lateral  
14 transmissivity in the Culebra will be within the degree of uncertainty accounted for by the use  
15 of conditioned transmissivity fields.

16  
17 Thus, the existing features associated with shallow dissolution and changes due to further  
18 shallow dissolution are accounted for in performance assessment calculations through the use  
19 of multiple transmissivity fields.

20  
21 *SCR.1.1.5.1.2 Lateral Dissolution*

22  
23 Lateral dissolution takes place when percolating groundwater dissolves halite at the top of the  
24 Salado, causing collapse of the overlying Rustler with consequent changes in hydrogeological  
25 properties. Nash Draw, some 5 miles (8 kilometers) to the west of the WIPP site, is the most  
26 prominent lateral dissolution feature in the region. An average lateral dissolution rate of from  
27 6 to 8 miles (10 to 13 kilometers) per million years has been calculated by Bachman et al.  
28 (1973, 39) for the Salado based on the assumption that the edge of the salt has moved from the  
29 Capitan Reef to its present position over the past 7 to 8 million years. A vertical dissolution  
30 rate of 0.06 mile (0.1 kilometer) per million years has similarly been calculated by Bachman  
31 (1974, 71; 1980, 97; 1981, 3) using dated ash layers. Although these are average rates and  
32 may be exceeded during particular climate states or by advancing tongues ahead of the main  
33 dissolution front, these rates indicate that dissolution of the Salado at the edge of the WIPP  
34 site would not take place for some 225,000 years, and an additional 2 to 3 million years would  
35 be required for dissolution to reach the repository horizon.

36  
37 Lateral dissolution may also have affected the Rustler directly. In the vicinity of Nash Draw,  
38 halite is absent from all the units of the Rustler. Further east, towards the WIPP site, halite  
39 progressively appears in younger units. This has led many investigators to conclude that  
40 halite has been dissolved from the Rustler by groundwater (see, for example, Lambert 1983,  
41 Bachman 1984, and Lowenstein 1987). A sedimentological analysis of the Rustler in 1988  
42 led Holt and Powers (Appendix FAC) to conclude that halite had either not been formed or  
43 had dissolved soon after deposition and, therefore, that only limited lateral dissolution has  
44 occurred since Permian times. Even if post-depositional dissolution has taken place, the

1 period over which it occurred is longer than the regulatory period. Lateral dissolution has  
2 therefore been eliminated from performance assessment calculations on the basis of low  
3 consequence to the performance of the disposal system.

#### 4 5 *SCR.1.1.5.1.3 Deep Dissolution*

6  
7 Deep dissolution refers to the dissolution of salt or other evaporite minerals in a formation at  
8 depth (see Section 2.1.6.2). Deep dissolution is distinguished from shallow and lateral  
9 dissolution not only by depth, but also by the origin of the water. Dissolution by groundwater  
10 from deep water-bearing zones can lead to the formation of cavities. Collapse of overlying  
11 beds leads to the formation of **collapse breccias** if the overlying rocks are brittle or to  
12 deformation if the overlying rocks are ductile. If dissolution is extensive, **breccia pipes** or  
13 **solution chimneys** may form above the cavity. These pipes may reach the surface or pass  
14 upwards into fractures and then into microcracks that do not extend to the surface. Breccia  
15 pipes may also form through the downward percolation of meteoric waters, as discussed  
16 earlier. Deep dissolution is of concern because it could accelerate contaminant transport  
17 through the creation of vertical flow paths that bypass low-permeability units in the Rustler.  
18 If dissolution occurred within or beneath the waste panels themselves, there could be  
19 increased circulation of groundwater through the waste as well as a breach of the Salado host  
20 rock.

21  
22 Features identified as being the result of deep dissolution are present along the northern and  
23 eastern margins of the Delaware Basin. In addition to features that have a surface expression  
24 or that appear within potash mine workings, deep dissolution has been cited by Anderson et  
25 al. (1972, 81) as the cause of lateral variability within evaporite sequences in the lower  
26 Salado. Observations concerning various features ascribed to deep dissolution are considered  
27 in the following subsections.

#### 28 29 *SCR.1.1.5.1.4 Solution Chimneys*

30  
31 Exposures of the McNutt Potash Member of the Salado within a mine near Nash Draw have  
32 shown a solution pipe containing cemented brecciated fragments of formations higher in the  
33 stratigraphic sequence. At the surface, this feature is marked by a dome, and similar domes  
34 have been interpreted as dissolution features. The depth of dissolution has not been  
35 confirmed, but the collapse structures led Anderson (1978, 52) and Snyder et al. (1982, 65) to  
36 postulate dissolution of the Capitan Limestone at depth; collapse of the Salado, Rustler, and  
37 younger formations; and subsequent dissolution and hydration by downward percolating  
38 waters. San Simon Sink (see Section 2.1.6.2), some 20 miles (35 kilometers) east-southeast  
39 of the WIPP site, has also been interpreted as a solution chimney. Subsidence has occurred  
40 there in historical times according to Nicholson and Clebsch (1961, 14), suggesting that  
41 dissolution at depth is still taking place. Whether this is the result of downwards-percolating  
42 surface water or of deep groundwater has not been confirmed. The association of these

1 dissolution features with the inner margin of the Capitan Reef suggest that they owe their  
2 origins, if not their continued development, to groundwaters derived from the Capitan  
3 Limestone.

4  
5 *SCR.1.1.5.1.5 Dissolution within the Castile and Lower Salado Formations*

6  
7 The Castile contains sequences of varved anhydrite and carbonate (that is, laminae deposited  
8 on a cyclical basis) that can be correlated between several boreholes. On the basis of these  
9 deposits, a basin-wide uniformity in the depositional environment of the Castile evaporites  
10 was assumed. The absence of varves from all or part of a sequence and the presence of  
11 brecciated anhydrite beds have been interpreted by Anderson et al. (1972) as evidence of  
12 dissolution. Holt and Powers (Appendix FAC) have questioned the assumption of a uniform  
13 depositional environment and contend that the anhydrite beds are lateral equivalents of halite  
14 sequences without significant postdepositional dissolution. Wedges of brecciated anhydrite  
15 along the margin of the Castile have been interpreted by Robinson and Powers (1987, 78) as  
16 gravity-driven clastic deposits, rather than the result of deep dissolution.

17  
18 Localized depressions at the top of the Castile and inclined geophysical marker units at the  
19 base of the Salado have been interpreted by Davies (1983, 45) as the result of deep dissolution  
20 and subsequent collapse or deformation of overlying rocks. The postulated cause of this  
21 dissolution was circulation of undersaturated groundwaters from the Bell Canyon Formation  
22 (hereafter referred to as the Bell Canyon). Additional boreholes (notably WIPP-13, WIPP-32,  
23 and DOE-2) and geophysical logging led Borns and Shaffer (1985) to conclude that the  
24 features interpreted by Davies as being dissolution features are the result of irregularities at  
25 the top of the Bell Canyon. These irregularities led to localized depositional thickening of the  
26 Castile and lower Salado sediments.

27  
28 *SCR.1.1.5.1.6 Collapse Breccias at Basin Margins*

29  
30 Collapse breccias are present at several places around the margins of the Delaware Basin.  
31 Their formation is attributed to relatively fresh groundwater from the Capitan Limestone that  
32 forms the margin of the basin. Collapse breccias corresponding to features on geophysical  
33 records that have been ascribed to deep dissolution have not been found in boreholes away  
34 from the margins. These features have been reinterpreted as the result of early dissolution  
35 prior to the deposition of the Salado. This topic is discussed further in Section 2.1.6.2.

36  
37 *SCR.1.1.5.1.7 Summary of Deep Dissolution*

38  
39 Deep dissolution features have been identified within the Delaware Basin, but only in  
40 marginal areas underlain by Capitan Reef. There is a low probability that deep dissolution  
41 will occur sufficiently close to the waste panels over the regulatory period to affect  
42 groundwater flow in the immediate region of the WIPP. Deep dissolution at the WIPP site  
43 has therefore been eliminated from performance assessment calculations on the basis of low  
44 probability of occurrence over the next 10,000 years.

1 SCR.1.1.5.2 Mineralization

2  
3 *The effects of fracture infills have been eliminated from performance assessment calculations*  
4 *on the basis of beneficial consequence to the performance of the disposal system.*

5  
6 Precipitation of minerals as **fracture infills** can reduce hydraulic conductivities. The  
7 distribution of infilled fractures in the Culebra closely parallels the spatial variability of lateral  
8 transmissivity in the Culebra (see Section SCR.1.1.5.1). The secondary gypsum veins in the  
9 Rustler have not been dated. Strontium isotope studies (Siegel et al. 1991, 5-53 to 5-57)  
10 indicate that the infilling minerals are locally derived from the host rock rather than  
11 extrinsically derived, and it is inferred that they reflect an early phase of mineralization and  
12 are not associated with recent meteoric waters.

13  
14 Stable isotope geochemistry in the Rustler has also provided information on mineral stabilities  
15 in these strata. Both Chapman (1986, 31) and Lambert and Harvey (1987, 207) imply that the  
16 mineralogical characteristics of units above the Salado have been stable or subject to only  
17 minor changes under the various recharge conditions that have existed during the past 0.6  
18 million year—the period since the formation of the Mescalero caliche and the establishment  
19 of a pattern of climate change and associated changes in recharge that led to present-day  
20 hydrogeological conditions. No changes in climate are expected other than those experienced  
21 during this period, and for this reason, no changes are expected in the mineralogical  
22 characteristics other than those expressed by the existing variability of fracture infills and  
23 diagenetic textures. Formation of fracture infills will reduce transmissivities and will  
24 therefore be of beneficial consequence to the performance of the disposal system.

25  
26 **SCR.1.2 Subsurface Hydrological FEPs**

27  
28 This section discusses FEPs relating to the natural groundwater system at the WIPP site and  
29 FEPs that may lead to changes in its flow and chemical characteristics.

30  
31 SCR.1.2.1 Groundwater Characteristics

32  
33 *Saturated groundwater flow, unsaturated groundwater flow, fracture flow, and the effects of*  
34 *preferential pathways are accounted for in performance assessment calculations. Density*  
35 *effects on groundwater flow have been eliminated from performance assessment calculations*  
36 *on the basis of low consequence to the performance of the disposal system.*

37  
38 **Saturated groundwater flow, unsaturated groundwater flow, and fracture flow** are  
39 accounted for in performance assessment calculations. Groundwater flow is discussed in  
40 Sections 2.2.1, 6.4.5, and 6.4.6.

41  
42 The most transmissive unit in the Rustler, and hence the most significant potential pathway  
43 for transport of radionuclides to the accessible environment, is the Culebra. The properties of  
44 Culebra groundwaters are not homogeneous, and spatial variations in groundwater density

(Section 2.2.1.4.1.2) could influence the rate and direction of groundwater flow. A comparison of the gravity-driven flow component and the pressure-driven component in the Culebra, however, shows that only in the region to the south of the WIPP are head gradients low enough for density gradients to be significant (Davies 1989, 53). Accounting for this variability would rotate groundwater flow vectors towards the east (down-dip) and hence fluid in the high transmissivity zone would move away from the zone. Excluding brine density variations within the Culebra from performance assessment calculations is therefore a conservative assumption, and **density effects on groundwater flow** have been eliminated from performance assessment calculations on the basis of low consequence to the performance of the disposal system.

The hydrogeologic properties of the Culebra are also spatially variable. This variability, including the **effects of preferential pathways**, is accounted for in performance assessment calculations in the estimates of transmissivity and aquifer thickness.

#### SCR.1.2.2 Changes in Groundwater Flow

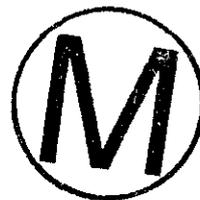

*Changes in groundwater flow arising from saline intrusion, freshwater intrusion, or natural gas intrusion have been eliminated from performance assessment calculations on the basis of a low probability of occurrence over 10,000 years. Natural thermal effects on groundwater flow have been eliminated from performance assessment calculations on the basis of low consequence to the performance of the disposal system. A hydrological response to earthquakes has been eliminated from performance assessment calculations on the basis of low consequence to the performance of the disposal system.*

##### SCR.1.2.2.1 Saline Intrusion

No natural events or processes have been identified that could result in **saline intrusion** into units above the Salado or cause a significant increase in fluid density. Natural saline intrusion has therefore been eliminated from performance assessment calculations on the basis of low probability of occurrence over the next 10,000 years. Saline intrusion arising from human-initiated events such as drilling into a pressurized brine pocket is discussed in Section SCR.3.3.

##### SCR.1.2.2.2 Freshwater Intrusion

A number of FEPs, including climate change, can result in changes in infiltration and recharge (see Section SCR.1.5.3). These changes will affect the height of the water table and hence could affect groundwater flow in the Rustler through changes in head gradients. The generally low transmissivity of the Dewey Lake and the Rustler, however, will prevent any significant changes in groundwater density from occurring within the Culebra over the timescales for which increased precipitation and recharge are anticipated. No other natural events or processes have been identified that could result in **freshwater intrusion** into units above the Salado or cause a significant decrease in fluid density. Freshwater intrusion has

1 therefore been eliminated from performance assessment calculations on the basis of low  
2 probability of occurrence over the next 10,000 years.

3  
4 *SCR.1.2.2.3 Thermal Effects*

5  
6 The geothermal gradient in the region of the WIPP has been measured at about 50°C per mile  
7 (30°C per kilometer). Given the generally low permeability in the region, and the limited  
8 thickness of units in which groundwater flow occurs (for example the Culebra), natural  
9 convection will be too weak to have a significant effect on groundwater flow. No natural  
10 FEPs have been identified that could significantly alter the temperature distribution of the  
11 disposal system or give rise to **thermal effects on groundwater flow**. Such effects have  
12 therefore been eliminated from performance assessment calculations on the basis of low  
13 consequence to the performance of the disposal system.

14  
15 *SCR.1.2.2.4 Natural Gas Intrusion*

16  
17 Hydrocarbon resources are present in formations beneath the WIPP (Section 2.3.1.2), and  
18 natural gas is extracted from the Morrow Formation. These reserves are, however, some  
19 14,000 feet (4,200 meters) below the surface, and no natural events or processes have been  
20 identified that could result in **natural gas intrusion** into the Salado or the units above.  
21 Natural gas intrusion has therefore been eliminated from performance assessment calculations  
22 on the basis of low probability of occurrence over the next 10,000 years.

23  
24 *SCR.1.2.2.5 Hydrological Effects of Seismic Activity*

25  
26 There are a variety of **hydrological responses to earthquakes**. Some of these responses,  
27 such as changes in surface-water flow directions, result directly from fault movement. Others,  
28 such as changes in subsurface water chemistry and temperature, probably result from changes  
29 in flow pathways along the fault or fault zone. According to Bredehoeft et al. (1987, 139),  
30 further away from the region of fault movement two types of changes to groundwater levels  
31 may take place as a result of changes in fluid pressure:

- 32
- 33 • The passage of seismic waves through a rock mass causes a volume change, inducing a  
34 transient response in the fluid pressure, which may be observed as a short-lived  
35 fluctuation of the water level in wells.
  - 36  
37 • Changes in volume strain can cause long-term changes in water level. A buildup of  
38 strain occurs prior to rupture and is released during an earthquake. The consequent  
39 change in fluid pressure may be manifested by the drying up or reactivation of springs  
40 some distance from the region of the epicenter.

41  
42 Fluid pressure changes induced by the transmission of seismic waves can produce changes of  
43 up to several meters in groundwater levels in wells, even at distances of thousands of  
44 kilometers from the epicenter. These changes are temporary, however, and levels typically

1 return to pre-earthquake levels in a few hours or days. Changes in fluid pressure arising from  
2 changes in volume strain persist for much longer periods, but they are only potentially  
3 consequential in tectonic regimes where there is a significant buildup of strain. The regional  
4 tectonics of the Delaware Basin indicate that such a buildup has a low probability of occurring  
5 over the next 10,000 years (Section SCR.1.1.2).

6  
7 The expected level of seismic activity in the region of the WIPP will be of low consequence to  
8 the performance of the disposal system in terms of groundwater flow or contaminant  
9 transport. Changes in groundwater levels resulting from more distant earthquakes will be too  
10 short in duration to be significant. Thus, the hydrological effects of earthquakes have been  
11 eliminated from performance assessment calculations on the basis of low consequence to the  
12 performance of the disposal system.

### 13 **SCR.1.3 Subsurface Geochemical FEPs**

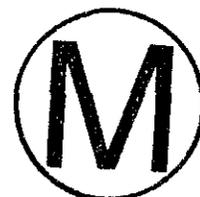

#### 14 **SCR.1.3.1 Groundwater Geochemistry**

15  
16  
17  
18 *Groundwater geochemistry in the hydrological units of the disposal system is accounted for in*  
19 *performance assessment calculations.*

20  
21 The most important aspect of **groundwater geochemistry** in the region of the WIPP in terms  
22 of chemical retardation and colloid stability is salinity. Groundwater geochemistry is  
23 discussed in detail in Sections 2.2 and 2.4 and summarized here. The Delaware Mountain  
24 Group, Castile, and Salado contain basinal brines. Waters in the Castile and Salado are at or  
25 near halite saturation. Above the Salado, groundwaters are also relatively saline, and  
26 groundwater quality is poor in all of the permeable units. Waters from the Culebra vary  
27 spatially in salinity and chemistry. They range from saline sodium chloride-rich waters to  
28 brackish calcium sulfate-rich waters. In addition, a range of magnesium to calcium ratios has  
29 been observed, and some waters reflect the influence of potash mining activities, having  
30 elevated potassium to sodium ratios. Waters from the Santa Rosa are generally of better  
31 quality than any of those from the Rustler. Salado and Castile brine geochemistry is  
32 accounted for in performance assessment calculations of the actinide source term (Section  
33 6.4.3.4). Culebra brine geochemistry is accounted for in the retardation factors used in  
34 performance assessment calculations of actinide transport (see Section 6.4.6.2).

#### 35 **SCR.1.3.2 Changes in Groundwater Chemistry**

36  
37  
38 *The effects of saline or freshwater intrusion and of dissolution on groundwater chemistry*  
39 *have been eliminated from performance assessment calculations on the basis of low*  
40 *consequence to the performance of the disposal system. Changes in groundwater Eh and pH*  
41 *have been eliminated from performance assessment calculations on the basis of low*  
42 *consequence to the performance of the disposal system.*

1 Natural changes in the groundwater chemistry of the Culebra and other units that resulted  
2 from **saline intrusion** or **freshwater intrusion** could potentially affect chemical retardation  
3 and the stability of colloids. **Changes in groundwater Eh** and **groundwater pH** could also  
4 affect the migration of radionuclides (see Sections SCR.2.5.5 and SCR.2.5.6). No natural  
5 events or processes have been identified that could result in saline intrusion into units above  
6 the Salado, and the magnitude of any natural temporal variation due to the **effects of**  
7 **dissolution** on groundwater chemistry, or due to changes in recharge is likely to be no greater  
8 than the present spatial variation. These FEPs related to the effects of future natural changes  
9 in groundwater chemistry have been eliminated from performance assessment calculations on  
10 the basis of low consequence to the performance of the disposal system.

11  
12 **SCR.1.4 Geomorphological FEPs**

13  
14 SCR.1.4.1 Physiography

15  
16 *Relevant aspects of the physiography, geomorphology, and topography of the region around*  
17 *the WIPP are accounted for in performance assessment calculations.*

18  
19 **Physiography** and geomorphology are discussed in detail in Section 2.1.4, and are accounted  
20 for in the setup of the performance assessment calculations (Section 6.4.2).

21  
22 SCR.1.4.2 Meteorite Impact

23  
24 *Disruption arising from the impact of a large meteorite has been eliminated from*  
25 *performance assessment calculations on the basis of low probability of occurrence over*  
26 *10,000 years.*

27  
28 Meteors frequently enter the earth's atmosphere, but most of these are small and burn up  
29 before reaching the ground. Of those that reach the ground, most produce only small impact  
30 craters that would have no effect on the postclosure integrity of a repository 2,150 feet  
31 (650 meters) below the ground surface. While the depth of a crater may be only one-eighth of  
32 its diameter, the depth of the disrupted and brecciated material is typically one-third of the  
33 overall crater diameter (Grieve 1987, 248). Direct disruption of waste at the WIPP would  
34 only occur with a crater larger than 1.1 miles (1.8 kilometers) in diameter. Even if waste were  
35 not directly disrupted, the **impact of a large meteorite** could create a zone of fractured rocks  
36 beneath and around the crater. The extent of such a zone would depend on the rock type. For  
37 sedimentary rocks, the zone may extend to a depth of half the crater diameter or more (Dence  
38 et al. 1977, 263). The impact of a meteorite causing a crater larger than 0.6 mile (1 kilometer)  
39 in diameter could thus fracture the Salado above the repository.

40  
41 Geological evidence for meteorite impacts on earth is rare because many meteorites fall into  
42 the oceans and erosion and sedimentation serve to obscure craters that form on land. Dietz  
43 (1961) estimated that meteorites that cause craters larger than 0.6 mile (1 kilometer) in  
44 diameter strike the earth at the rate of about one every 10,000 years (equivalent to about

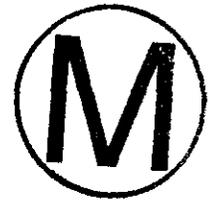

1  $2 \times 10^{-13}$  impacts per square kilometer per year). Using observations from the Canadian  
 2 Shield, Hartmann (1965, 161) estimated a frequency of between  $0.8 \times 10^{-13}$  and  $17 \times 10^{-13}$  per  
 3 square kilometer per year for impacts causing craters larger than 0.6 mile (1 kilometer).  
 4 Frequencies estimated for larger impacts in studies reported by Grieve (1987, 263) can be  
 5 extrapolated to give a rate of about  $1.3 \times 10^{-12}$  per square kilometer per year for craters larger  
 6 than 0.6 mile (1 kilometer). It is commonly assumed that meteorite impacts are randomly  
 7 distributed across the earth's surface, although Halliday (1964, 267 – 277) calculated that the  
 8 rate of impact in polar regions would be some 50 to 60 percent of that in equatorial regions.  
 9 The frequencies reported by Grieve (1987) would correspond to an overall rate of about one  
 10 per 1,000 years on the basis of a random distribution.

11  
 12 Assuming the higher estimated impact rate of  $17 \times 10^{-13}$  impacts per square kilometer per year  
 13 for impacts leading to fracturing of sufficient extent to affect a deep repository and assuming a  
 14 repository footprint of 0.9 mile  $\times$  1.0 mile (1.4 kilometers  $\times$  1.6 kilometers) for the WIPP  
 15 yields a frequency of about  $4 \times 10^{-12}$  impacts per year for a direct hit above the repository.  
 16 This impact frequency is several orders of magnitude below the screening limit of  $10^{-4}$  per  
 17 10,000 years provided in 40 CFR § 194.32(d).

18  
 19 Meteorite hits directly above the repository footprint are not the only impacts of concern,  
 20 however, because large craters may disrupt the waste panels even if the center of the crater is  
 21 outside the repository area. It is possible to calculate the frequency of meteorite impacts that  
 22 could disrupt a deep repository such as the WIPP by using the conservative model of a  
 23 cylinder of rock fractured to a depth equal to one-half the crater diameter, as shown in Figure  
 24 SCR-1. The area within which a meteorite could impact the repository is calculated by  
 25

$$S_D = \left(L + 2 \times \frac{D}{2}\right) \times \left(W + 2 \times \frac{D}{2}\right) ,$$

26 where

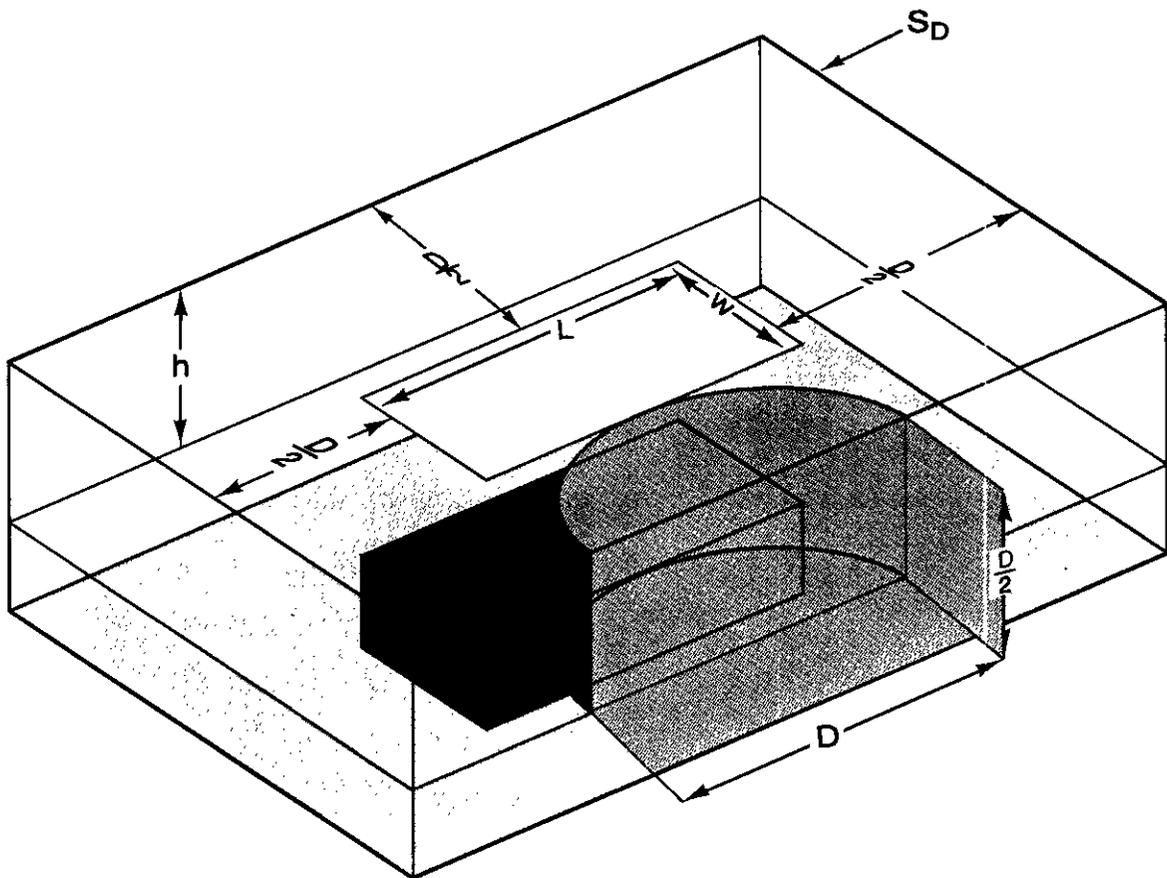

- 27  $L$  = length of the repository footprint (kilometers)
- 28  $W$  = width of the repository footprint (kilometers)
- 29  $D$  = diameter of the impact crater (kilometers)
- 30  $S_D$  = area of the region where the crater would disrupt the repository (square  
 31 kilometers).

32  
 33 There are insufficient data on meteorites that have struck the earth to derive a distribution  
 34 function for the size of craters directly. Using meteorite impacts on the moon as an analogy,  
 35 however, Grieve (1987, 257) derived the following distribution function:  
 36

$$F_D \propto D^{-1.8} ,$$

37 where

- 38  $F_D$  = frequency of impacts resulting in craters larger than  $D$  (impacts per square  
 39 kilometer per year).

CCA-SCR001-0

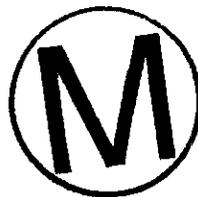

Figure SCR-1. The Critical Region for Meteorite Impacts That Could Result in Fracturing of the Repository Horizon

**THIS PAGE INTENTIONALLY LEFT BLANK**

1 If  $f(D)$  denotes the frequency of impacts giving craters of diameter  $D$ , then the frequency of  
 2 impacts giving craters larger than  $D$  is

$$F_D = \int_D^{\infty} f(D) dD$$

3 and

$$f(D) = F_1 \times 1.8 \times D^{-2.8} ,$$

4 where

5  $F_1$  = frequency of impacts resulting in craters larger than 1 kilometer (impacts per  
 6 square kilometer per year)

7  $f(D)$  = frequency of impacts resulting in craters of diameter  $D$  (impacts per square  
 8 kilometer per year).

9  
 10 The overall frequency of meteorite impacts that could disrupt or fracture the repository is thus  
 11 given by

$$N = \int_{2h}^{\infty} f(D) \times S_D dD ,$$

12 where

13  $h$  = depth to repository (kilometers)

14  $N$  = frequency of impacts leading to disruption of the repository (impacts per year)

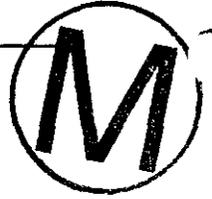

$$N = 1.8F_1[1.8LW(2h)^{-1.8} + 0.8(L+W)(2h)^{-0.8} - 0.2(2h)^{0.2}] .$$

15  
 16 If it is assumed that the repository is located at a depth of 650 meters and has a footprint area  
 17 of 0.9 mile  $\times$  1.0 mile (1.4 kilometers  $\times$  1.6 kilometers) and that meteorites creating craters  
 18 larger than 1 kilometer in diameter hit the earth at a frequency ( $F_1$ ) of  $17 \times 10^{-13}$  impacts per  
 19 square kilometer per year, then the above equation gives a frequency of approximately  
 20  $1.3 \times 10^{-11}$  impacts per year for impacts disrupting the repository. If impacts are randomly  
 21 distributed over time, this corresponds to a probability of  $1.3 \times 10^{-7}$  over 10,000 years.

22  
 23 Similar calculations have been performed that indicate rates of impact of between  $10^{-12}$  and  
 24  $10^{-13}$  per year for meteorites large enough to disrupt a deep repository (see, for example,  
 25 Hartmann 1979, Kärnbränslesakerhet 1978, Claiborne and Gera 1974, Cranwell et al. 1990,  
 26 and Thorne 1992). Meteorite impact can thus be eliminated from performance assessment  
 27 calculations on the basis of low probability of occurrence over 10,000 years.

28  
 29 Assuming a random or nearly random distribution of meteorite impacts, cratering at any  
 30 location is inevitable given sufficient time. Although repository depth and host-rock lithology  
 31 may reduce the consequences of a meteorite impact, there are no repository locations or  
 32 engineered systems that can reduce the probability of impact over 10,000 years.

1 SCR.1.4.3 Denudation

2  
3 SCR.1.4.3.1 Weathering

4  
5 *The effects of chemical and mechanical weathering have been eliminated from performance*  
6 *assessment calculations on the basis of low consequence to the performance of the disposal*  
7 *system.*

8  
9 **Mechanical weathering** and **chemical weathering** are assumed to be occurring at or near the  
10 surface around the WIPP site, through processes such as exfoliation and leaching. The extent  
11 of these processes is limited and they will contribute little to the overall rate of erosion in the  
12 area or to the availability of material for other erosional processes. The effects of chemical  
13 and mechanical weathering have been eliminated from performance assessment calculations  
14 on the basis of low consequence to the performance of the disposal system.

15  
16 SCR.1.4.3.2 Erosion

17  
18 *The effects of fluvial and aeolian erosion and mass wasting in the region of the WIPP have*  
19 *been eliminated from performance assessment calculations on the basis of low consequence to*  
20 *the performance of the disposal system.*

21  
22 The geomorphological regime on the Mescalero Plain (Los Medaños) in the region of the  
23 WIPP is dominated by aeolian processes. Dunes are present in the area, and although some  
24 are stabilized by vegetation, **aeolian erosion** will occur as they migrate across the area. Old  
25 dunes will be replaced by new dunes, and no significant changes in the overall thickness of  
26 aeolian material are likely to occur.

27  
28 Currently, precipitation in the region of the WIPP is too low (about 13 inches [33 centimeters]  
29 per year) to cause perennial streams, and the relief in the area is too low for extensive sheet  
30 flood erosion during storms. An increase in precipitation to around 24 inches (61 centimeters)  
31 per year in cooler climatic conditions could result in perennial streams, but the nature of the  
32 relief and the presence of dissolution hollows and sinks will ensure that these streams remain  
33 small. Significant **fluvial erosion** is not expected during the next 10,000 years.

34  
35 **Mass wasting** (the downslope movement of material caused by the direct effect of gravity) is  
36 important only in terms of sediment erosion in regions of steep slopes. In the vicinity of the  
37 WIPP, mass wasting will be insignificant under the climatic conditions expected over the next  
38 10,000 years.

39  
40 Erosion from wind, water, and mass wasting will continue in the WIPP region throughout the  
41 next 10,000 years at rates similar to those occurring at present. These rates are too low to  
42 affect the performance of the disposal system significantly. Thus, the effects of fluvial and  
43 aeolian erosion and mass wasting have been eliminated from performance assessment  
44 calculations on the basis of low consequence to the performance of the disposal system.

1 SCR.1.4.3.3 Sedimentation

2  
3 *The effects of aeolian, fluvial, and lacustrine deposition and sedimentation in the region of the*  
4 *WIPP have been eliminated from performance assessment calculations on the basis of low*  
5 *consequence to the performance of the disposal system.*

6  
7 The geomorphological regime on the Mescalero Plain (Los Medaños) in the region of the  
8 WIPP is dominated by aeolian processes, but although some dunes are stabilized by  
9 vegetation, no significant changes in the overall thickness of aeolian material are expected to  
10 occur. Vegetational changes during periods of wetter climate may further stabilize the dune  
11 fields, but **aeolian deposition** is not expected to significantly increase the overall thickness of  
12 the superficial deposits.

13  
14 The limited extent of water courses in the region of the WIPP, under both present-day  
15 conditions and under the expected climatic conditions, will restrict the amount of **fluvial**  
16 **deposition** and **lacustrine deposition** in the region.

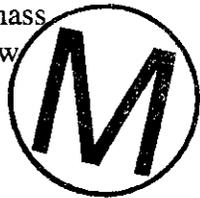

17  
18 **Mass wasting** may be significant if it results in dams or modifies streams. In the region  
19 around the WIPP, the Pecos River forms a significant water course some 12 miles  
20 (19 kilometers) away, but the broadness of its valley precludes either significant mass wasting  
21 or the formation of large impoundments.

22  
23 Sedimentation from wind, water, and mass wasting is expected to continue in the WIPP  
24 region throughout the next 10,000 years at the low rates similar to those occurring at present.  
25 These rates are too low to significantly affect the performance of the disposal system. Thus,  
26 the effects of aeolian, fluvial, and lacustrine deposition and sedimentation resulting from mass  
27 wasting have been eliminated from performance assessment calculations on the basis of low  
28 consequence.

29  
30 SCR.1.4.4 Soil Development

31  
32 *Soil development has been eliminated from performance assessment calculations on the basis*  
33 *of low consequence to the performance of the disposal system.*

34  
35 The Mescalero caliche is a well-developed calcareous remnant of an extensive soil profile  
36 across the WIPP site and adjacent areas. Although this unit may be up to 10 feet (3 meters)  
37 thick, it is not continuous and does not prevent infiltration to the underlying formations. At  
38 Nash Draw, this caliche, dated in Lappin et al. (1989, 2-4) at 410,000 to 510,000 years old, is  
39 present in collapse blocks, indicating some growth of Nash Draw in the late Pleistocene.  
40 Localized gypsite spring deposits about 25,000 years old occur along the eastern flank of Nash  
41 Draw, but the springs are not currently active. The Berino soil, interpreted as 333,000 years  
42 old (Rosholt and McKinney 1980, Table 5), is a thin soil horizon above the Mescalero caliche.  
43 The persistence of these soils on the Livingston Ridge and the lack of deformation indicates  
44 the relative stability of the WIPP region over the past half-million years.

1 Continued growth of caliche may occur in the future but will be of low consequence in terms  
2 of its effect on infiltration. Other soils in the area are not extensive enough to affect the  
3 amount of infiltration that reaches underlying aquifers. **Soil development** has been  
4 eliminated from performance assessment calculations on the basis of low consequence to the  
5 performance of the disposal system.

6  
7 **SCR.1.5 Surface Hydrological FEPs**

8  
9 SCR.1.5.1 Fluvial

10  
11 *Stream and river flow has been eliminated from performance assessment calculations on the*  
12 *basis of low consequence to the performance of the disposal system.*

13  
14 No perennial streams are present at the WIPP site, and there is no evidence in the literature  
15 indicating that such features existed at this location since the Pleistocene (see, for example,  
16 Powers et al. 1978; and Bachman 1974, 1981, and 1987). The Pecos River is approximately  
17 12 miles (19 kilometers) from the WIPP site and more than 300 feet (90 meters) lower in  
18 elevation. **Stream and river flow** have been eliminated from performance assessment  
19 calculations on the basis of low consequence to the performance of the disposal system.

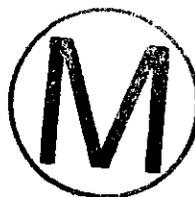

20  
21 SCR.1.5.2 Lacustrine

22  
23 *The effects of surface water bodies have been eliminated from performance assessment*  
24 *calculations on the basis of low consequence to the performance of the disposal system.*

25  
26 No standing **surface water bodies** are present at the WIPP site, and there is no evidence in  
27 the literature indicating that such features existed at this location during or after the  
28 Pleistocene (see, for example, Powers et al. 1978; and Bachman 1974, 1981, and 1987). In  
29 Nash Draw, lakes and spoil ponds associated with potash mines are located at elevations  
30 100 feet (30 meters) below the elevation of the land surface at the location of the waste panels.  
31 There is no evidence in the literature to suggest that Nash Draw was formed by stream erosion  
32 or was at any time the location of a deep body of standing water, although shallow playa lakes  
33 have existed there at various times. Based on these factors, the formation of large lakes is  
34 unlikely and the formation of smaller lakes and ponds is of little consequence to the  
35 performance of the disposal system. The effects of surface water bodies have therefore been  
36 eliminated from performance assessment calculations on the basis of low consequence to the  
37 performance of the disposal system.

38  
39 SCR.1.5.3 Groundwater Recharge and Discharge

40  
41 *Groundwater recharge, infiltration, and groundwater discharge are accounted for in*  
42 *performance assessment calculations.*

1 The groundwater basin described in Section 2.2.1.4 is governed by flow from areas where the  
2 water table is high to areas where the water table is low. The height of the water table is  
3 governed by the amount of **groundwater recharge** reaching the water table, which in turn is a  
4 function of the vertical hydraulic conductivity and the partitioning of precipitation between  
5 evapotranspiration, runoff, and **infiltration**. Flow within the Rustler is also governed by the  
6 amount of **groundwater discharge** that takes place from the basin. In the region around the  
7 WIPP, the principal discharge areas are along Nash Draw and the Pecos River. Groundwater  
8 flow modeling accounts for infiltration, recharge, and discharge (Sections 2.2.1.4 and  
9 6.4.10.2).

10  
11 **SCR.1.5.4 Changes in Surface Hydrology**

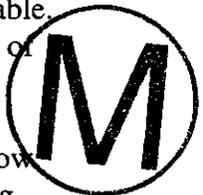

12  
13 *Changes in groundwater recharge and discharge arising as a result of climate change are*  
14 *accounted for in performance assessment calculations. The effects of river flooding and lake*  
15 *formation have been eliminated from performance assessment calculations on the basis of low*  
16 *consequence to the performance of the disposal system.*

17  
18 Changes in recharge may affect groundwater flow and radionuclide transport in units such as  
19 the Culebra and Magenta dolomites. Changes in the surface environment driven by natural  
20 climate change are expected to occur over the next 10,000 years (see Section SCR.1.6.2).  
21 Groundwater basin modeling (Section 2.2.1.4) indicates that a change in recharge will affect  
22 the height of the water table in the area of the WIPP, and that this will in turn affect the  
23 direction and rate of groundwater flow.

24  
25 The present-day water table in the vicinity of the WIPP is within the Dewey Lake at about  
26 3,215 feet (980 meters) above mean sea level (Section 2.2.1.4.2.1). An increase in recharge  
27 relative to present-day conditions would raise the water table, potentially as far as the ground  
28 surface locally. Similarly, a decrease in recharge could result in a lowering of the water table.  
29 The low transmissivity of the Dewey Lake and the Rustler ensures that any such lowering of  
30 the water table will be at a slow rate, and lateral discharge from the groundwater basin is  
31 expected to persist for several thousand years after any decrease in recharge. Under the  
32 anticipated changes in climate over the next 10,000 years, the water table will not fall below  
33 the base of the Dewey Lake, and dewatering of the Culebra is not expected to occur during  
34 this period (Section 2.2.1.4).

35  
36 **Changes in groundwater recharge and discharge** are accounted for in performance  
37 assessment calculations through definition of the boundary conditions for flow and transport  
38 in the Culebra (Section 6.4.9).

39  
40 Intermittent flooding of stream channels and the formation of shallow lakes will occur in the  
41 WIPP region over the next 10,000 years. These may have a short-lived and local effect on the  
42 height of the water table, but are unlikely to affect groundwater flow in the Culebra.

1 Future occurrences of playa lakes or other longer-term floods will be remote from the WIPP  
2 and will have little consequence on system performance in terms of groundwater flow at the  
3 site. There is no reason to believe that any impoundments or lakes could form over the WIPP  
4 site itself. Thus, **river flooding** and **lake formation** have been eliminated from performance  
5 assessment calculations on the basis of low consequence to the performance of the disposal  
6 system.

7  
8 ***SCR.1.6 Climatic FEPs***

9  
10 This section discusses climate change and glaciation in the WIPP region.

11  
12 ***SCR.1.6.1 Climate***

13  
14 *Precipitation and temperature are accounted for in performance assessment calculations.*

15  
16 The climate and meteorology of the region around the WIPP are described in Section 2.5.2.  
17 Precipitation in the region is low (about 13 inches [33 centimeters] per year) and temperatures  
18 are moderate with a mean annual temperature of about 63°F (17°C). **Precipitation** and  
19 **temperature** are important controls on the amount of recharge that reaches the groundwater  
20 system and are accounted for in performance assessment calculations by use of a sampled  
21 parameter for scaling flow velocity in the Culebra (Section 6.4.9 and Appendix PAR,  
22 Parameter 48).

23  
24 ***SCR.1.6.2 Climate Change***

25  
26 ***SCR.1.6.2.1 Meteorological***

27  
28 *Climate change is accounted for in performance assessment calculations.*

29  
30 **Climate changes** are instigated by changes in the earth's orbit, which affect the amount of  
31 insolation, and by feedback mechanisms within the atmosphere and hydrosphere. Models of  
32 these mechanisms, combined with interpretations of the geological record, suggest that the  
33 climate will become cooler and wetter in the WIPP region during the next 10,000 years as a  
34 result of natural causes. Other changes, such as fluctuations in radiation intensity from the  
35 sun and variability within the many feedback mechanisms, will modify this climatic response  
36 to orbital changes. The available evidence suggests that these changes will be less extreme  
37 than those arising from orbital fluctuations.

38  
39 The effect of a change to cooler and wetter conditions is considered to be an increase in the  
40 amount of recharge, which in turn will affect the height of the water table (see Section  
41 SCR.1.5.4). The height of the water table across the groundwater basin is an important  
42 control on the rate and direction of groundwater flow within the Culebra (see Section 2.2.1.4),  
43 and hence potentially on transport of radionuclides released to the Culebra through the shafts  
44 or intrusion boreholes. Climate change is accounted for in performance assessment

1 calculations through a sampled parameter used to scale groundwater flow velocity in the  
2 Culebra (Section 6.4.9 and Appendix PAR, Parameter 48).

3  
4 *SCR.1.6.2.2 Glaciation*

5  
6 *Glaciation and the effects of permafrost have been eliminated from performance assessment*  
7 *calculations on the basis of low probability of occurrence over 10,000 years.*

8  
9 No evidence exists to suggest that the northern part of the Delaware Basin has been covered  
10 by continental glaciers at any time since the beginning of the Paleozoic Era. During the  
11 maximum extent of continental **glaciation** in the Pleistocene Epoch, glaciers extended into  
12 northeastern Kansas at their closest approach to southeastern New Mexico. There is no  
13 evidence that alpine glaciers formed in the region of the WIPP during the Pleistocene glacial  
14 periods.

15  
16 According to the theory that relates the periodicity of climate change to perturbations in the  
17 earth's orbit, a return to a full glacial cycle within the next 10,000 years is highly unlikely  
18 (Imbrie and Imbrie 1980, 951).

19  
20 Thus, glaciation has been eliminated from performance assessment calculations on the basis  
21 of low probability of occurrence over the next 10,000 years. Similarly, a number of processes  
22 associated with the proximity of an ice sheet or valley glacier, such as **permafrost** and  
23 accelerated slope erosion (solifluction) have been eliminated from performance assessment  
24 calculations on the basis of low probability of occurrence over the next 10,000 years.

25  
26 *SCR.1.7 Marine FEPs*

27  
28 *SCR.1.7.1 Seas*

29  
30 *The effects of estuaries, seas, and oceans have has been eliminated from performance*  
31 *assessment calculations on the basis of low consequence to the performance of the disposal*  
32 *system.*

33  
34 The WIPP site is more than 480 miles (800 kilometers) from the Pacific Ocean and from the  
35 Gulf of Mexico. **Estuaries** and **seas and oceans** have therefore been eliminated from  
36 performance assessment calculations on the basis of low consequence to the disposal system.

37  
38 *SCR.1.7.2 Marine Sedimentology*

39  
40 *The effects of coastal erosion, and marine sediment transport and deposition have been*  
41 *eliminated from performance assessment calculations on the basis of low consequence to the*  
42 *performance of the disposal system.*

1 The WIPP site is more than 480 miles (800 kilometers) from the Pacific Ocean and Gulf of  
2 Mexico. The effects of **coastal erosion** and **marine sediment transport and deposition**  
3 have therefore been eliminated from performance assessment calculations on the basis of low  
4 consequence to the performance of the disposal system.

5  
6 **SCR.1.7.3 Sea Level Changes**

7  
8 *The effects of both short-term and long-term sea level changes have been eliminated from*  
9 *performance assessment calculations on the basis of low consequence to the performance of*  
10 *the disposal system.*

11  
12 The WIPP site is some 3,330 feet (1,015 meters) above sea level. Global **sea level change**  
13 may result in sea levels as much as 460 feet (140 meters) below that of the present day during  
14 glacial periods, according to Chappell and Shackleton (1986, 138). This can have marked  
15 effects on coastal aquifers. During the next 10,000 years, the global sea level can be expected  
16 to drop towards this glacial minimum, but this will not affect the groundwater system in the  
17 vicinity of the WIPP. Short-term changes in sea level, brought about by events such as  
18 meteorite impact, tsunamis, seiches, and hurricanes may raise water levels by several tens of  
19 meters. Such events have a maximum duration of a few days and will have no effect on the  
20 surface or groundwater systems at the WIPP site. Anthropogenic-induced global warming has  
21 been conjectured by Warrick and Oerlemans (1990, 278) to result in longer-term sea level  
22 rise. The magnitude of this rise, however, is not expected to be more than a few meters, and  
23 such a variation will have no effect on the groundwater system in the WIPP region. Thus, the  
24 effects of both short-term and long-term sea level changes have been eliminated from  
25 performance assessment calculations on the basis of low consequence to the performance of  
26 the disposal system.

27  
28 **SCR.1.8 *Ecological FEPs***

29  
30 **SCR.1.8.1 Flora and Fauna**

31  
32 *The effects of the natural plants, animals, and microbes (flora and fauna) in the region of the*  
33 *WIPP have been eliminated from performance assessment calculations on the basis of low*  
34 *consequence to the performance of the disposal system.*

35  
36 The terrestrial and aquatic ecology of the region around the WIPP is described in  
37 Section 2.4.1. The **plants** in the region are predominantly shrubs and grasses. The most  
38 conspicuous **animals** in the area are jackrabbits and cottontails. **Microbes** are presumed to be  
39 present within the thin soil horizons. The effects of this flora and fauna in the region have  
40 been eliminated from performance assessment calculations on the basis of low consequence to  
41 the performance of the disposal system.

1 SCR.1.8.2 Changes in Flora and Fauna

2  
3 *The effects of natural ecological development likely to occur in the region of the WIPP have*  
4 *been eliminated from performance assessment calculations on the basis of low consequence to*  
5 *the performance of the disposal system.*

6  
7 The region around the WIPP is sparsely vegetated as a result of the climate and poor soil  
8 quality. Wetter periods are expected during the regulatory period, but botanical records  
9 indicate that, even under these conditions, dense vegetation will not be present in the region  
10 (Swift 1992; see Appendix CLI, 17). The effects of the indigenous fauna are of low  
11 consequence to the performance of the disposal system and no natural events or processes  
12 have been identified that would lead to a change in this fauna that would be of consequence to  
13 system performance. **Natural ecological development** in the region of the WIPP has  
14 therefore been eliminated from performance assessment calculations on the basis of low  
15 consequence to the performance of the disposal system.

16  
17 **SCR.2 Waste- and Repository-Induced FEPs**

18  
19 In Section SCR.2, the DOE discusses waste- and repository-induced FEPs in the context of  
20 the FEP categorization scheme presented in Table SCR-2. Waste- and repository-induced  
21 FEPs are potentially relevant to the analyses conducted to evaluate compliance with 40 CFR  
22 § 191.13, 40 CFR § 191.15, and 40 CFR § 191.24. Note that the categories concerned with  
23 geology and mechanics (SCR.2.3), hydrology and fluid dynamics (SCR.2.4), and  
24 geochemistry and chemistry (SCR.2.5) relate to structure, fluid flow, and fluid chemistry,  
25 respectively, within the repository and the rest of the disposal system. The categories  
26 concerned with contaminant transport modes (SCR.2.6) and processes (SCR.2.7), and ecology  
27 (SCR.2.8) relate to the potential migration of radionuclides through the disposal system to the  
28 accessible environment. FEPs presented in Table SCR-2 are printed in bold in the text of the  
29 FEP screening discussions.

30  
31 **SCR.2.1 Waste and Repository Characteristics**

32  
33 **SCR.2.1.1 Repository Characteristics**

34  
35 *The WIPP repository disposal geometry is accounted for in performance assessment*  
36 *calculations.*

37  
38 **Disposal geometry** is described in Chapter 3.0 and is accounted for in the setup of  
39 performance assessment calculations (Section 6.4.3).

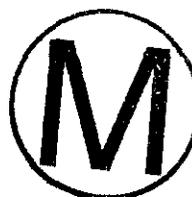

40  
41 **SCR.2.1.2 Waste Characteristics**

42  
43 *The waste inventory and heterogeneity of the waste forms are accounted for in performance*  
44 *assessment calculations.*

**Legend:**

- UP FEPs accounted for in the assessment calculations for undisturbed performance for 40 CFR § 191.13 (as well as 40 CFR § 191.15 and Subpart C of 40 CFR Part 191).
- DP FEPs accounted for (in addition to all UP FEPs) in the assessment calculations for disturbed performance for 40 CFR § 191.13.
- SO-R FEPs eliminated from performance assessment calculations on the basis of regulations provided in 40 CFR Part 191 and criteria provided in 40 CFR Part 194.
- SO-C FEPs eliminated from performance assessment (and compliance assessment) calculations on the basis of consequence.
- SO-P FEPs eliminated from performance assessment (and compliance assessment) calculations on the basis of low probability of occurrence.

Waste characteristics, comprising the **waste inventory** and the **heterogeneity of waste forms**, are described in Chapter 4.0. The waste inventory is accounted for in performance assessment calculations in deriving the dissolved actinide source term and gas generation rates (Sections 6.4.3.5 and 6.4.3.3). The distribution of contact-handled (CH) and remote-handled (RH) transuranic (TRU) waste within the repository leads to room scale heterogeneity of the waste forms, which is accounted for in performance assessment calculations when considering the potential activity of waste material encountered during inadvertent borehole intrusion (Section 6.4.7).

1 SCR.2.1.3 Container Characteristics

2  
3 *The container material inventory is accounted for in performance assessment calculations.*  
4 *The container form has been eliminated from performance assessment calculations on the*  
5 *basis of low consequence to the performance of the disposal system.*  
6

7 The **container material inventory** is described in Chapter 4.0, and is accounted for in  
8 performance assessment calculations through the estimation of gas generation rates  
9 (Section 6.4.3.3). **Container form** will affect container strength through the shape and  
10 dimensions of the container and affect heat dissipation through container volume and surface  
11 area. Long-term container performance has been eliminated from performance assessment  
12 calculations on the basis of low consequence to the performance of the disposal system  
13 (Section SCR.2.3.8). Heat generation from the waste is also considered of low consequence  
14 to the performance of the disposal system (Section SCR.2.2.2). Container form has, therefore,  
15 been eliminated from performance assessment calculations on the basis of low consequence to  
16 the performance of the disposal system.

17  
18 SCR.2.1.4 Seal Characteristics

19  
20 *The seal geometry and seal physical properties are accounted for in performance assessment*  
21 *calculations. The seal chemical composition has been eliminated from performance*  
22 *assessment calculations on the basis of beneficial consequence to the performance of the*  
23 *disposal system.*  
24

25 Seal (shaft seals, panel closures, and drift closures) characteristics, including **seal geometry**  
26 and **seal physical properties**, are described in Chapter 3.0 and are accounted for in  
27 performance assessment calculations through the representation of the seal system in  
28 BRAGFLO and the permeabilities assigned to the seal materials (Section 6.4.4). The effect of  
29 shaft **seal chemical composition** on actinide speciation and mobility is discussed in Section  
30 SCR.2.5.2 and has been eliminated from performance assessment calculations on the basis of  
31 beneficial consequence to the performance of the disposal system.

32  
33 SCR.2.1.5 Backfill Characteristics

34  
35 *The backfill chemical composition is accounted for in performance assessment calculations.*  
36 *Backfill physical properties have been eliminated from performance assessment calculations*  
37 *on the basis of low consequence to the performance of the disposal system.*  
38

39 A chemical conditioner (hereafter referred to as backfill) will be added to the disposal room to  
40 buffer the chemical environment. The backfill characteristics are described in Section 6.4.3.4.  
41 The mechanical and thermal effects of backfill are discussed in Sections SCR.2.3.8.1 and  
42 SCR.2.5.7.2, respectively, where they have been eliminated from performance assessment  
43 calculations on the basis of low consequence to the performance of the disposal system.  
44 Backfill will result in an initial permeability for the disposal room lower than that of an empty

1 cavity, so neglecting the hydrological effects of backfill is a conservative assumption with  
2 regard to brine inflow and radionuclide migration. Thus, **backfill physical properties** have  
3 been eliminated from performance assessment calculations on the basis of low consequence to  
4 the performance of the disposal system. The chemical effects of backfill are discussed in  
5 Section SCR.2.5.2.1 and the **backfill chemical composition** is accounted for in performance  
6 assessment calculations in deriving the dissolved and colloidal actinide source terms  
7 (Section 6.4.3).

8  
9 **SCR.2.1.6 Postclosure Monitoring**

10  
11 *The potential effects of postclosure monitoring have been eliminated from performance*  
12 *assessment calculations on the basis of low consequence to the performance of the disposal*  
13 *system.*

14  
15 **Postclosure monitoring** is required by 40 CFR § 191.14(b) as an assurance requirement to  
16 “detect substantial and detrimental deviations from expected performance.” The DOE has  
17 designed the monitoring program (see Appendix MON) so that the monitoring methods  
18 employed are not detrimental to the performance of the disposal system. Long-term  
19 monitoring would not be expected to lead to a need for remedial activities. In summary, the  
20 effects of monitoring have been eliminated from performance assessment calculations on the  
21 basis of low consequence to the performance of the disposal system.

22  
23 **SCR.2.2 *Radiological FEPs***

24  
25 **SCR.2.2.1 Radioactive Decay**

26  
27 *Radioactive decay and ingrowth are accounted for in performance assessment calculations.*

28  
29 **Radionuclide decay and ingrowth** are accounted for in performance assessment calculations  
30 (see Section 6.4.12.4).

31  
32 **SCR.2.2.2 Heat from Radioactive Decay**

33  
34 *The effects of temperature increases as a result of radioactive decay have been eliminated*  
35 *from performance assessment calculations on the basis of low consequence to the*  
36 *performance of the disposal system.*

37  
38 Radioactive decay of the waste emplaced in the repository will generate heat. The importance  
39 of **heat from radioactive decay** depends on the effects that the induced temperature changes  
40 would have on mechanics (Section SCR.2.3.7), fluid flow (Section SCR.2.4.3), and  
41 geochemical processes (Section SCR.2.5). For example, extreme temperature increases could  
42 result in thermally induced fracturing, regional uplift, or thermally driven flow of gas and  
43 brine in the vicinity of the repository.

1 According to the Waste Acceptance Criteria (WAC) (see Chapter 4.0), the design basis for the  
2 WIPP requires that the thermal loading does not exceed 10 kilowatts per acre. The WAC also  
3 require that the thermal power generated by waste in an RH-TRU container shall not exceed  
4 300 watts, but the WAC do not limit the thermal power of CH-TRU waste containers.

5  
6 A numerical study to calculate induced temperature distributions and regional uplift is  
7 reported in DOE (1980, 9-149 to 9-150). This study involved estimation of the thermal power  
8 of CH-TRU waste containers. The DOE (1980, 9-149) analysis assumed the following:

- 9  
10 • All CH-TRU waste drums and boxes contain the maximum permissible quantity of  
11 plutonium. According to the WAC, the fissionable radionuclide content for CH-TRU  
12 waste containers shall be no greater than 200 grams per 0.21 cubic meter drum and  
13 350 grams per 1.8 cubic meter standard waste box (<sup>239</sup>Pu fissile gram equivalents).  
14  
15 • The plutonium in CH-TRU waste containers is weapons grade material producing heat  
16 at 0.0024 watts per gram. Thus, the thermal power of a drum is approximately 0.5  
17 watts and that of a box is approximately 0.8 watts.  
18  
19 • Approximately  $3.7 \times 10^5$  cubic meters of CH-TRU waste are distributed within a  
20 repository enclosing an area of  $7.3 \times 10^5$  square meters. This is a conservative  
21 assumption in terms of quantity and density of waste within the repository, because the  
22 maximum capacity of the WIPP is  $1.756 \times 10^5$  cubic meters for all waste (as specified  
23 by the Land Withdrawal Act [LWA]) to be placed in an enclosed area of  
24 approximately  $5.1 \times 10^5$  square meters.  
25  
26 • Half of the CH-TRU waste volume is placed in drums and half in boxes so that the  
27 repository will contain approximately  $9 \times 10^5$  drums and  $10^5$  boxes. Thus, a calculated  
28 thermal power of 2.8 kilowatts per acre (0.7 watts per square meter) of heat is  
29 generated by the CH-TRU waste.  
30  
31 • Insufficient RH-TRU waste is emplaced in the repository to influence the total thermal  
32 load.

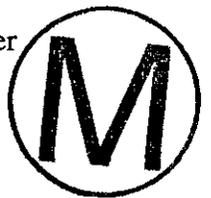

33  
34 Under these assumptions, Thorne and Rudeen (1981) estimated the long-term temperature  
35 response of the disposal system to waste emplacement. Calculations assumed a uniform  
36 initial power density of 2.8 kilowatts per acre (0.7 watts per square meter) which decreases  
37 over time. Thorne and Rudeen (1981) attributed this thermal load to RH-TRU waste, but the  
38 DOE (1980), more appropriately, attributed this thermal load to CH-TRU waste based on the  
39 assumptions listed above. Thorne and Rudeen (1981) estimated the maximum rise in  
40 temperature at the center of a repository to be 1.6°C at 80 years after waste emplacement.

41  
42 Sanchez and Trellue (1996) estimated the maximum thermal power of an RH-TRU waste  
43 container. The Sanchez and Trellue (1996) analysis involved inverse shielding calculations to  
44 evaluate the thermal power of an RH-TRU container corresponding to the maximum

1 permissible surface dose; according to the WAC, the maximum allowable surface dose  
2 equivalent for RH-TRU containers is 1000 rem per hour. The following calculational steps  
3 were taken in the Sanchez and Trellue (1996) analysis:  
4

- 5 • Calculate the absorbed dose rate for gamma radiation corresponding to the maximum  
6 surface dose equivalent rate of 1000 rem per hour. Beta and alpha radiation are not  
7 included in this calculation because such particles will not penetrate the waste matrix  
8 or the container in significant quantities. Neutrons are not included in the analysis  
9 because, according to the WAC, the maximum dose rate from neutrons is 270 millirem  
10 per hour, and the corresponding neutron heating rate will be insignificant.  
11
- 12 • Calculate the exposure rate for gamma radiation corresponding to the absorbed dose  
13 rate for gamma radiation.  
14
- 15 • Calculate the gamma flux density at the surface of a RH-TRU container corresponding  
16 to the exposure rate for gamma radiation. Assuming the gamma energy is 1.0  
17 megaelectron volts, the maximum allowable gamma flux density at the surface of a  
18 RH-TRU container is about  $5.8 \times 10^8$  gamma rays per square centimeter per second.  
19
- 20 • Determine the distributed gamma source strength, or gamma activity, in an RH-TRU  
21 container from the surface gamma flux density. The source is assumed to be shielded  
22 such that the gamma flux is attenuated by the container and by absorbing material in  
23 the container. The level of shielding depends on the matrix density. Scattering of the  
24 gamma flux, with loss of energy, is also accounted for in this calculation through  
25 inclusion of a gamma buildup factor. The distributed gamma source strength is  
26 determined assuming a uniform source in a right cylindrical container. The maximum  
27 total gamma source (gamma curies) is then calculated for a RH-TRU container  
28 containing 0.89 cubic meters of waste. For the waste of greatest expected density  
29 (about 6,000 kilograms per cubic meter), the gamma source is about  $2 \times 10^4$  curies per  
30 cubic meter.  
31
- 32 • Calculate the total curie load of a RH-TRU container (including alpha and beta  
33 radiation) from the gamma load. The ratio of the total curie load to the gamma curie  
34 load was estimated through examination of the radionuclide inventory presented in  
35 Appendix BIR. The gamma curie load and the total curie load for each radionuclide  
36 listed in the WIPP BIR were summed. Based on these summed loads the ratio of total  
37 curie load to gamma curie load of RH-TRU waste was calculated to be 1.01.  
38
- 39 • Calculate the thermal load of a RH-TRU container from the total curie load. The ratio  
40 of thermal load to curie load was estimated through examination of the radionuclide  
41 inventory presented in Appendix BIR. The thermal load and the total curie load for  
42 each radionuclide listed in the WIPP BIR were summed. Based on these summed  
43 loads the ratio of thermal load to curie load of RH-TRU waste was calculated to be  
44 about 0.0037 watts per curie. For a gamma source of  $2 \times 10^4$  curies per cubic meter,

1 the maximum permissible thermal load of a RH-TRU container is about 70 watts per  
2 cubic meter. Thus, the maximum thermal load of a RH-TRU container is about 60  
3 watts, and the WAC upper limit of 300 watts will not be achieved.  
4

5 Note that Sanchez and Trelue (1996) calculated the average thermal load for a RH-TRU  
6 container to be less than 1 watt. Also, the total RH-TRU heat load is less than 10 percent of  
7 the total heat load in the WIPP. Thus, the total thermal load of the RH-TRU waste will not  
8 significantly affect the average rise in temperature in the repository resulting from decay of  
9 CH-TRU waste.  
10

11 Temperature increases will be greater at locations where the thermal power of an RH-TRU  
12 container is 60 watts, if any such containers are emplaced. Sanchez and Trelue (1996)  
13 estimated the temperature increase at the surface of a 60 watt RH-TRU waste container. Their  
14 analysis involved solution of a steady-state thermal conduction problem with a constant heat  
15 source term of 70 watts per cubic meter. These conditions represent conservative assumptions  
16 because the thermal load will decrease with time as the radioactive waste decays. The  
17 temperature increase at the surface of the container was calculated to be about 3°C.  
18

19 In summary, analysis has shown that the average temperature increase in the WIPP repository,  
20 due to radioactive decay of the emplaced CH- and RH-TRU waste, will be less than 2°C.  
21 Temperature increases of about 3°C may occur in the vicinity of RH-TRU containers with the  
22 highest allowable thermal load of about 60 watts (based on the maximum allowable surface  
23 dose equivalent for RH-TRU containers). Potential heat generation from nuclear criticality is  
24 discussed in Section SCR.2.2.3 and exothermic reactions are discussed in Section SCR.2.5.7.  
25 The effects of repository temperature changes on mechanics (Section SCR.2.3.7), fluid flow  
26 (Section SCR.2.4.3), and geochemical processes (SCR.2.5) have been eliminated from  
27 performance assessment calculations on the basis of low consequence to the performance of  
28 the disposal system.  
29

### 30 SCR.2.2.3 Nuclear Criticality

31  
32 *Nuclear criticality has been eliminated from performance assessment calculations on the*  
33 *basis of low probability of occurrence over 10,000 years.*  
34

35 **Nuclear criticality** refers to a sustained fission reaction that may occur if fissile radionuclides  
36 reach both a sufficiently high concentration and total mass (where the latter parameter  
37 includes the influence of enrichment of the fissile radionuclides). In the subsurface, the  
38 primary effect of a nuclear reaction is the production of **heat**.  
39

40 The possibility of a nuclear criticality in the waste disposal region has been eliminated from  
41 performance assessment calculations because of the low initial concentration of the fissile  
42 radionuclides (that is, the WAC limits the fissile radionuclides in the CH- and RH-TRU  
43 containers) and because no credible mechanism exists to further concentrate the fissile  
44 radionuclides after closure. To elaborate, possible mechanisms for concentration in the waste

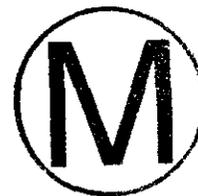

1 disposal region include high solubility, compaction, sorption, and precipitation. First, the  
2 maximum solubility of  $^{239}\text{Pu}$  in the WIPP repository, the most abundant fissile radionuclide, is  
3 orders of magnitude lower than necessary to create a critical solution. The same is true for  
4  $^{235}\text{U}$ , the other primary fissile radionuclide. Second, the waste is assumed to be compacted by  
5 repository processes to one fourth its original volume. This compaction is still an order of  
6 magnitude too disperse (many orders of magnitude too disperse if neutron absorbers that  
7 prevent criticality (for example,  $^{238}\text{U}$ ) are included). Third, any potential sorbents in the  
8 waste would be fairly uniformly distributed throughout the waste disposal region;  
9 consequently, concentration of fissile radionuclides in localized areas through sorption is  
10 improbable. Fourth, precipitation requires significant localized changes in brine chemistry;  
11 small local variations are insufficient to separate substantial amounts of  $^{239}\text{Pu}$  from other  
12 actinides in the waste disposal region that can prevent a criticality (for example, 11 times  
13 more  $^{238}\text{U}$  is present than  $^{239}\text{Pu}$ ).

14  
15 The possibility of a criticality in the far field along the transport pathways to the accessible  
16 environment (primarily the Culebra and marker beds in the Salado) has been eliminated from  
17 performance assessment calculations because a geometry favorable for criticality will not be  
18 achieved by fissile radionuclides that may become immobile in the Culebra or marker beds.  
19 As discussed in Section 6.4.6.2 and Appendix MASS Section 15, the porosity in the dolomite  
20 consists of intergranular porosity, vugs, microscopic fractures, and macroscopic fractures. As  
21 discussed in Section 6.4.5.2, porosity in the marker beds consists of partially healed fractures  
22 that may dilate as pressure increases. Advective flow in both units occurs mostly through  
23 macroscopic fractures. Consequently, any potential deposition through precipitation or  
24 sorption is constrained by the depth to which precipitation and sorption occur away from  
25 fractures. This geometry is not favorable for fission reactions and eliminates the possibility of  
26 a criticality. Thus, nuclear criticality has been eliminated from performance assessment  
27 calculations on the basis of low probability of occurrence. The potential for nuclear criticality  
28 is discussed in more detail by Rechar et al. (1996). Potential heat generation from  
29 radioactive decay is discussed in Section SCR.2.2.2 and exothermic reactions are discussed in  
30 Section SCR.2.5.7.

#### 31 32 SCR.2.2.4 Radiological Effects on Material Properties

33  
34 *Radiological effects on the properties of the waste, container, and seals, have been eliminated*  
35 *from performance assessment calculations on the basis of low consequence to the*  
36 *performance of the disposal system.*

37  
38 Ionizing radiation can change the physical properties of many materials. Strong radiation  
39 fields could lead to damage of waste matrices, brittleness of the metal containers, and  
40 disruption of any crystalline structure in the seals. However, the low level of activity of the  
41 waste in the WIPP is unlikely to generate a strong radiation field. In addition, performance  
42 assessment calculations assume instantaneous container failure and waste dissolution  
43 according to the source-term model (see Section 6.4.3.4, 6.4.3.5, and 6.4.3.6). Therefore,  
44 **radiological effects on the properties of the waste, containers, and seals, have been**

1 eliminated from performance assessment calculations on the basis of low consequence to the  
2 performance of the disposal system.

3  
4 **SCR.2.3 Geological and Mechanical FEPs**

5  
6 **SCR.2.3.1 Excavation-Induced Fracturing**

7  
8 *Excavation-induced host rock fracturing through formation of a DRZ and changes in stress*  
9 *are accounted for in performance assessment calculations.*

10  
11 Construction of the repository has caused local **excavation-induced changes in stress** in the  
12 surrounding rock as discussed in Section 3.3.1.5. This has led to failure of intact rock around  
13 the opening, creating a **disturbed rock zone** of fractures. On completion of the WIPP  
14 excavation, the extent of the induced stress field perturbation will be sufficient to have caused  
15 dilation and fracturing in the anhydrite layers a and b, marker bed (MB) 139, and, possibly,  
16 MB138. The creation of the DRZ around the excavation and the disturbance of the anhydrite  
17 layers and marker beds will alter the permeability and effective porosity of the rock around the  
18 repository, providing enhanced pathways for flow of gas and brine between the waste-filled  
19 rooms and the nearby interbeds. This excavation-induced, host-rock fracturing is accounted  
20 for in performance assessment calculations (Section 6.4.5.3).

21  
22 The DRZ around repository shafts could provide pathways for flow from the repository to  
23 hydraulically conductive units above the repository horizon. The effectiveness of long-term  
24 shaft seals is dependent upon the seals providing sufficient backstress for salt creep to heal the  
25 DRZ around them, so that connected flow paths out of the repository horizon will cease to  
26 exist. These factors are considered in the current seal design.

27  
28 **SCR.2.3.2 Rock Creep**

29  
30 *Salt creep in the Salado and resultant changes in the stress field are accounted for in*  
31 *performance assessment calculations.*

32  
33 **Salt creep** will lead to **changes in the stress field**, compaction of the waste and containers,  
34 and consolidation of the long-term components of the sealing system. It will also tend to  
35 close fractures in the DRZ, leading to reductions in porosity and permeability, increases in  
36 pore fluid pressure, and reductions in fluid flow rates in the repository. Salt creep in the  
37 Salado is accounted for in performance assessment calculations (Section 6.4.3.1). The long-  
38 term repository seal system relies on the consolidation of the crushed-salt seal material and  
39 healing of the DRZ around the seals to achieve a low permeability under stresses induced by  
40 salt creep. Seal performance is discussed further in Section SCR.2.3.8.2.

1 SCR.2.3.3 Roof Falls

2  
3 *The potential effects of roof falls on flow paths are accounted for in performance assessment*  
4 *calculations.*

5  
6 Instability of the DRZ could lead to localized **roof falls** in the first few hundred years. If  
7 instability of the DRZ causes roof falls, development of the DRZ may be sufficient to disrupt  
8 the anhydrite layers above the repository, which may create a zone of rock containing  
9 anhydrite extending from the interbeds toward a waste-filled room. Fracture development is  
10 most likely to be induced as the rock stress and strain distributions evolve because of creep.  
11 In the long term, the effects of roof falls in the repository are likely to be minor because salt  
12 creep will reduce the void space and the potential for roof falls as well as leading to healing of  
13 any roof material that has fallen into the rooms. However, because of uncertainty in the  
14 process by which the disposal room DRZ heals, the flow model used in the performance  
15 assessment assumes that a higher permeability zone remains for the long term. Thus, the  
16 potential effects of roof falls on flow paths are accounted for in performance assessment  
17 calculations through appropriate ranges of the parameters describing the DRZ.

18  
19 SCR.2.3.4 Subsidence

20  
21 *Fracturing within units overlying the Salado and surface displacement caused by subsidence*  
22 *associated with repository closure has been eliminated from performance assessment*  
23 *calculations on the basis of low consequence to the performance of the disposal system. The*  
24 *potential for excavation or repository-induced subsidence to create large-scale rock*  
25 *fracturing and fluid flow paths between the repository and units overlying the Salado has*  
26 *been eliminated from performance assessment calculations on the basis of the low probability*  
27 *of occurrence over 10,000 years.*

28  
29 **Subsidence** through salt creep or roof collapse associated with excavation might affect the  
30 hydrologic properties of units above the repository and might cause **large-scale rock**  
31 **fracturing** between the repository horizon and the surface.

32  
33 The amount of subsidence that can occur as a result of salt creep closure or roof collapse in  
34 the WIPP excavation depends primarily on the volume of excavated rock, the initial and  
35 compressed porosities of the various emplaced materials (waste, backfill, panel and drift  
36 closures, and seals), the amount of inward creep of the repository walls, and the gas and fluid  
37 pressures within the repository. The DOE (Westinghouse 1994) has analyzed potential  
38 excavation-induced subsidence with the primary objective of determining the geomechanical  
39 advantage of backfilling the WIPP excavation. The DOE (Westinghouse 1994, 3-4 to 3-23)  
40 used mass conservation calculations, the influence function method, the National Coal Board  
41 empirical method, and the two-dimensional, finite-difference code, Fast Lagrangian Analysis  
42 of Continua (FLAC) to estimate subsidence for conditions ranging from no backfill to  
43 emplacement of a highly compacted crushed salt backfill. The DOE (Westinghouse 1994,

1 2-17 to 2-23) also investigated subsidence at potash mines located near the WIPP site to gain  
2 insight into the expected subsidence conditions at the WIPP and to calibrate the subsidence  
3 calculation methods.  
4

5 Subsidence over potash mines will be much greater than subsidence over the WIPP because of  
6 the significant differences in stratigraphic position, depth, extraction ratio, and layout. The  
7 WIPP site is located stratigraphically lower than the lowest potash mine, which is near the  
8 base of the McNutt Potash Member (hereafter called the McNutt). At the WIPP site, the base  
9 of the McNutt is about 490 feet (150 meters) above the repository horizon. Also, the WIPP  
10 rock extraction ratio in the waste disposal region will be about 22 percent, as compared to  
11 65 percent for the lowest extraction ratios within potash mines investigated by the DOE  
12 (Westinghouse 1994, 2-17).  
13

14 The DOE (Westinghouse 1994, 2-22) reported the maximum total subsidence at potash mines  
15 to be about 5 feet (1.5 meters). This level of subsidence has been observed to have caused  
16 surface fractures. However, the DOE (Westinghouse 1994, 2-23) found no evidence that  
17 subsidence over potash mines had caused fracturing sufficient to connect the mining horizon  
18 to water-bearing units or the landsurface. The level of disturbance caused by subsidence  
19 above the WIPP repository will be less than that associated with potash mining and thus, by  
20 analogy, will not create fluid flow paths between the repository and the overlying units.  
21

22 The various subsidence calculation methods used by the DOE (Westinghouse 1994, 3-4 to  
23 3-23) provided similar and consistent results, which support the premise that subsidence over  
24 the WIPP will be less than subsidence over potash mines. Estimates of maximum subsidence  
25 at the land surface for the cases of no backfill and highly compacted backfill are 2 feet (0.62  
26 meters) and 1.7 feet (0.52 meters), respectively. The mass conservation method gave the  
27 upper bound estimate of subsidence in each case. The surface topography in the WIPP area  
28 varies by more than 10 feet (3 meters), so the expected amount of repository-induced  
29 subsidence will not create a basin, and will not affect surface hydrology significantly. The  
30 DOE (Westinghouse 1994, Table 3-13) also estimated subsidence at the depth of the Culebra  
31 using the FLAC model, for the case of an empty repository (containing no waste or backfill).  
32 The FLAC analysis assumed the Salado to be halite and the Culebra to have anhydrite  
33 material parameters.  
34

35 Maximum subsidence at the Culebra was estimated to be 1.8 feet (0.56 meters). The vertical  
36 strain was concentrated in the Salado above the repository. Vertical strain was less than  
37 0.01 percent in units overlying the Salado and was close to zero in the Culebra (Westinghouse  
38 1994, Figure 3-40). The maximum horizontal displacement in the Culebra was estimated to  
39 be 0.08 feet (0.02 meters), with a maximum tensile horizontal strain of 0.007 percent. The  
40 DOE (Westinghouse 1994, 4-1 to 4-2) concluded that the induced strains in the Culebra will  
41 be uniformly distributed because no large-scale faults or discontinuities are present in the  
42 vicinity of the WIPP. Furthermore, strains of this magnitude would not be expected to cause  
43 extensive fracturing.  
44

1 At the WIPP site, the Culebra hydraulic conductivity varies spatially over approximately four  
 2 orders of magnitude, from  $1 \times 10^{-8}$  meters per second (0.4 meters per year) to  $1 \times 10^{-5}$  meters  
 3 per second (400 meters per year) (Section 2.2.1.4.1.2). Where transmissive horizontal  
 4 fractures exist, hydraulic conductivity in the Culebra is dominated by flow through the  
 5 fractures. An induced tensile vertical strain may result in an increase in fracture aperture and  
 6 corresponding increases in hydraulic conductivity. The magnitude of increase in hydraulic  
 7 conductivity can be estimated by approximating the hydrological behavior of the Culebra with  
 8 a simple conceptual model of fluid flow through a series of parallel fractures with uniform  
 9 properties. A conservative estimate of the change in hydraulic conductivity can be made by  
 10 assuming that all the vertical strain is translated to fracture opening (and none to rock  
 11 expansion). This method for evaluating changes in hydraulic conductivity is similar to that  
 12 used by the U.S. Environmental Protection Agency (EPA) in estimating the effects of  
 13 subsidence caused by potash mining (Peake 1996, EPA 1996, 9-38 to 9-60).

14  
 15 The equivalent porous medium hydraulic conductivity,  $K$  (meters per second), of a system of  
 16 parallel fractures can be calculated assuming the cubic law for fluid flow (Witherspoon et al.  
 17 1980):

$$K = \frac{w^3 \rho g N}{12 \mu D}$$

18  
 19 where  $w$  is the fracture aperture,  $\rho$  is the fluid density (taken to be 1,000 kilograms per cubic  
 20 meter),  $g$  is the acceleration due to gravity (9.79 meters per second squared),  $\mu$  is the fluid  
 21 viscosity (taken as 0.001 pascal seconds),  $D$  is the effective Culebra thickness (7.7 meters),  
 22 and  $N$  is the number of fractures.

23  
 24 For 10 fractures with a fracture aperture,  $w$ , of  $6 \times 10^{-5}$  meters, the Culebra hydraulic  
 25 conductivity,  $K$ , is approximately 7 meters per year ( $2 \times 10^{-7}$  meters per second). The values  
 26 of the parameters used in this calculation are within the range of those expected for the  
 27 Culebra at the WIPP site (Section 2.2.1.4.1.2).

28  
 29 The amount of opening of each fracture as a result of subsidence-induced tensile vertical  
 30 strain,  $\epsilon$ , (assuming rigid rock) is  $D\epsilon/N$  meters. Thus, for a vertical strain of 0.0001 meters  
 31 per meter, the fracture aperture,  $w$ , becomes approximately  $1.4 \times 10^{-4}$  meters. The Culebra  
 32 hydraulic conductivity,  $K$ , then increases to approximately 85 meters per year  
 33 ( $2.7 \times 10^{-6}$  meters per second). Thus, on the basis of a conservative estimate of vertical strain,  
 34 the hydraulic conductivity of the Culebra may increase by an order of magnitude. In the  
 35 performance assessment calculations, multiple realizations of the Culebra transmissivity field  
 36 are generated as a means of accounting for spatial variability and uncertainty (Appendix  
 37 TFIELD). A change in hydraulic conductivity of one order of magnitude through vertical  
 38 strain is within the range of uncertainty incorporated in the Culebra transmissivity field  
 39 through these multiple realizations. Thus, changes in the horizontal component of Culebra  
 40 hydraulic conductivity resulting from repository-induced subsidence have been eliminated  
 41 from performance assessment calculations on the basis of low consequence.

1 A similar calculation can be performed to estimate the change in vertical hydraulic  
2 conductivity in the Culebra as a result of a horizontal strain of 0.00007 meters per meter  
3 (Westinghouse 1994, 3-20). Assuming this strain to be distributed over about 1,000 fractures  
4 (neglecting rock expansion), with zero initial aperture, in a lateral extent of the Culebra of  
5 about 800 meters (Westinghouse 1994, Figure 3-39), then the subsidence-induced fracture  
6 aperture is approximately  $6 \times 10^{-5}$  meters. Using the values for  $\rho$ ,  $g$ , and  $\mu$ , above, the  
7 vertical hydraulic conductivity of the Culebra can then be calculated, through an equation  
8 similar to above, to be 7 meters per year ( $2 \times 10^{-7}$  meters per second). Thus, vertical hydraulic  
9 conductivity in the Culebra may be created as a result of repository-induced subsidence,  
10 although this is expected to be insignificant.

11  
12 In summary, as a result of observations of subsidence associated with potash mines in the  
13 vicinity of the WIPP, the potential for subsidence to create fluid flow paths between the  
14 repository and units overlying the Salado has been eliminated from performance assessment  
15 calculations on the basis of low probability. The effects of repository-induced subsidence on  
16 hydraulic conductivity in the Culebra have been eliminated from performance assessment  
17 calculations on the basis of low consequence to the performance of the disposal system.

#### 18 19 SCR.2.3.5 Effects of Fluid Pressure Changes

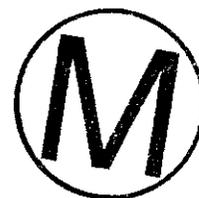

20  
21 *The mechanical effects of gas generation through pressurization and disruption due to gas*  
22 *flow are accounted for in performance assessment calculations.*

23  
24 The mechanical effects of gas generation, including the slowing of creep closure of the  
25 repository due to gas **pressurization**, and the fracturing of interbeds in the Salado through  
26 **disruption due to gas effects** are accounted for in performance assessment calculations  
27 (Sections 6.4.5.2 and 6.4.3.1).

#### 28 29 SCR.2.3.6 Effects of Explosions

30  
31 *The potential effects of gas explosions are accounted for in performance assessment*  
32 *calculations. Nuclear explosions have been eliminated from performance assessment*  
33 *calculations on the basis of low probability of occurrence over 10,000 years.*

34  
35 Explosive gas mixtures could collect in the head space above the waste in a closed panel. The  
36 most explosive gas mixture potentially generated will be a mixture of hydrogen, methane, and  
37 oxygen which will convert to carbon dioxide and water on ignition. This means that there is  
38 little likelihood of a **gas explosion** in the long term, because the rooms and panels are  
39 expected to become anoxic and oxygen depleted. Compaction through salt creep will also  
40 greatly reduce any void space in which the gas can accumulate. Analysis (see Appendix PCS)  
41 indicates that the most explosive mixture of hydrogen, methane, and oxygen will be present in  
42 the void space approximately 20 years after panel-closure emplacement. This possibility of an  
43 explosion prior to the occurrence of anoxic conditions is considered in the design of the  
44 operational panel closure. The effect of such an explosion on the DRZ is expected to be no

1 more severe than a roof fall, which is accounted for in the performance assessment  
2 calculations (Section SCR.2.3.3).

3  
4 For a **nuclear explosion** to occur, a critical mass of plutonium would have to undergo rapid  
5 compression to a high density. Even if a critical mass of plutonium could form in the system,  
6 there is no mechanism for rapid compression. Thus, nuclear explosions have been eliminated  
7 from performance assessment calculations on the basis of low probability of occurrence over  
8 10,000 years.

9  
10 **SCR.2.3.7 Thermal Effects**

11  
12 *The effects of thermally induced stress, differing thermal expansion of components, and*  
13 *thermal effects on material properties in the repository have been eliminated from*  
14 *performance assessment calculations on the basis of low consequence to performance of the*  
15 *disposal system.*

16  
17 **Thermally induced stress** could result in pathways for groundwater flow in the DRZ, in the  
18 anhydrite layers and marker beds, and through seals, or it could enhance existing pathways.  
19 Conversely, elevated temperatures will accelerate the rate of salt creep and mitigate fracture  
20 development. Thermal expansion could also result in uplift of the rock and ground surface  
21 overlying the repository, and thermal buoyancy forces could lift the waste upward in the salt  
22 rock.

23  
24 The distributions of thermal stress and strain changes depend on the induced temperature field  
25 and the **differing thermal expansion of repository components** of the repository, which  
26 depends on the components' elastic properties. Potentially, **thermal effects on material**  
27 **properties** (such as permeability and porosity) could affect the behavior of the repository.

28  
29 Radioactive decay (Section SCR.2.2.2), nuclear criticality (Section SCR.2.2.3), and  
30 exothermic reactions (Section SCR.2.5.7) are three possible sources of heat in the WIPP  
31 repository.

32  
33 DOE (1980) estimated that radioactive decay of CH-TRU waste will result in a maximum  
34 temperature rise at the center of the repository of 1.6°C at 80 years after waste emplacement  
35 (Section SCR.2.2.2). Sanchez and Trelue (1996) have shown that the total thermal load of  
36 RH-TRU waste will not significantly affect the average temperature increase in the repository  
37 (Section SCR.2.2.2). Temperature increases of about 3°C may occur at the locations of  
38 RH-TRU containers of maximum thermal power (60 watts). Material properties, such as  
39 porosity and permeability, are insensitive to temperature changes of this order.

40  
41 Argüello and Torres (1988) evaluated the thermomechanical effects of emplacing RH-TRU  
42 waste in the walls of a WIPP waste disposal room. Their analysis assumed that the RH-TRU  
43 waste canisters had a thermal power of 60 watts and were emplaced in a disposal room 8 feet  
44 (2.44 meters) apart, equivalent to an areal thermal loading of 10 kilowatts per acre (2.5 watts

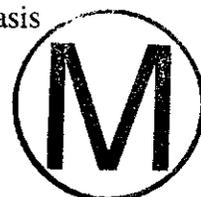

1 per square meter). This value of the thermal load is significantly greater than the total thermal  
2 load of the RH- and CH-TRU waste to be emplaced in the WIPP repository. The thermal and  
3 structural responses to the thermal load were evaluated for a six-year simulation period  
4 assuming temperature dependent elastic and creep behavior. At the end of this period, the  
5 temperature was calculated to have increased by a maximum of about 3°C. Vertical and  
6 horizontal room closures were about 4 percent and 7 percent greater, respectively, than under  
7 isothermal conditions and changes in stress were negligible. This structural response to  
8 temperature change is greater than the expected response in the WIPP repository, because the  
9 maximum expected temperature increase from radioactive decay is less than 3°C. Also, the  
10 differing thermal expansion of repository components will be insignificant at this magnitude  
11 of temperature change. Thus, radioactive decay-induced temperature changes will have  
12 negligible effects on the development of the stresses and strains in the repository after waste  
13 emplacement.

14  
15 Thorne and Rudeen (1981) calculated regional uplift and the effects of buoyancy forces  
16 resulting from a repository with a thermal power of 2.8 kilowatts per acre (0.7 watts per  
17 square meter). The calculated maximum displacement of a point in the repository at the top of  
18 the emplacement level was 10.4 millimeters, occurring at about 90 years after emplacement.  
19 The maximum surface uplift was calculated to be less than 6 millimeters at about 1,000 years  
20 after waste emplacement. This level of uplift will not affect the rock above the repository  
21 significantly.

22  
23 Nuclear criticality has been eliminated from performance assessment calculations on the basis  
24 of low probability of occurrence over 10,000 years (Section SCR.2.2.3).

25  
26 Temperature increases resulting from exothermic reactions are discussed in Section  
27 SCR.2.5.7. Potentially the most significant exothermic reactions are concrete hydration,  
28 backfill hydration, and aluminum corrosion. Hydration of the seal concrete could raise the  
29 temperature of the concrete to approximately 53°C and that of the surrounding salt to  
30 approximately 38°C one week after seal emplacement (see Section SCR.2.5.7.1). The  
31 thermomechanical effects of such temperature increases on the performance of the repository  
32 seals have been considered in the seal design program (Loken 1994; Loken and Chen 1995).  
33 The program has investigated the durability of large-scale concrete seals, and has formulated  
34 Salado mass concrete (SMC) with the aim of achieving the seal design targets reported in  
35 Wakeley et al. (1995), which include objectives to minimize thermally-induced cracking.  
36 According to Wakeley et al. (1995), the SMC will be prepared and emplaced at low  
37 temperatures in order to minimize the difference between the maximum concrete temperature  
38 and the ambient temperature in the repository. Temperature increases resulting from cement  
39 hydration will be low enough to mitigate thermal stresses and eliminate the potential for  
40 significant cracking. Loken (1994) and Loken and Chen (1995) examined the thermal and  
41 mechanical effects of emplacing large concrete seals in salt at the WIPP and showed that  
42 significant cracking of the seals will be unlikely (see Section SCR.2.5.7.1). Thus,  
43 thermomechanical effects associated with concrete hydration have been eliminated from  
44 performance assessment calculations on the basis of low consequence to the performance of

1 the disposal system. As discussed in Section SCR.2.5.7.2, the maximum temperature rise in  
2 the disposal panels as a consequence of backfill hydration will be less than 5°C, resulting  
3 from brine inflow following a drilling intrusion into a waste disposal panel. Note that active  
4 institutional controls will prevent drilling within the controlled area for 100 years after  
5 disposal. By this time, any heat generation by radioactive decay and concrete seal hydration  
6 will have decreased substantially, and the temperatures in the disposal panels will have  
7 reduced to close to initial values.

8  
9 Under similar conditions following a drilling event, aluminum corrosion could, at most, result  
10 in a short-lived (two years) temperature increase of about 6°C (see Section SCR.2.5.7.3).  
11 These calculated maximum heat generation rates resulting from aluminum corrosion and  
12 backfill hydration could not occur simultaneously because they are limited by brine  
13 availability; each calculation assumes that all available brine is consumed by the reaction of  
14 concern. Thus, the temperature rise of 6°C represents the maximum that could occur as a  
15 result of any combination of exothermic reactions occurring simultaneously. Temperature  
16 increases of this magnitude will have no significant effects on the stress and strain  
17 distributions within the disposal system.

18  
19 In summary, temperature changes in the disposal system will not cause significant thermal  
20 expansion in any of the repository components, will not cause significant buoyancy forces,  
21 will not result in significant fracture initiation or extension, and will not significantly affect  
22 material properties in the disposal system.

23  
24 Thus, the effects of thermally-induced stress, differing thermal expansion of components, and  
25 thermal effects on material properties in the repository have been eliminated from  
26 performance assessment calculations on the basis of low consequence to the performance of  
27 the disposal system.

28  
29 SCR.2.3.8 Mechanical Effects on Material Properties

30  
31 *Consolidation of waste is accounted for in performance assessment calculations. Container*  
32 *integrity has been eliminated from performance assessment calculations on the basis of*  
33 *beneficial consequence to the performance of the disposal system. Movement of containers*  
34 *and the mechanical effects of backfill have been eliminated from performance assessment*  
35 *calculations on the basis of low consequence to the performance of the disposal system.*  
36 *Consolidation of seals and mechanical degradation of seals are accounted for in performance*  
37 *assessment calculations. Flow through sealed WIPP investigation boreholes drilled from the*  
38 *surface has been eliminated from performance assessment calculations on the basis of low*  
39 *consequence to the performance of the disposal system. Flow through isolated, unsealed*  
40 *underground boreholes is accounted for in performance assessment calculations.*  
41

1 SCR.2.3.8.1 Consolidation of Waste and Container Performance

2  
3 **Consolidation of waste** is accounted for in performance assessment calculations in the  
4 modeling of creep closure of the disposal room (Section 6.4.3.1).

5  
6 Modeling of creep closure and waste dissolution and release conservatively assume immediate  
7 container failure. **Container integrity** has been eliminated from performance assessment  
8 calculations on the basis of beneficial consequence to the performance of the disposal system.

9  
10 The chemical conditioners or backfill added to the disposal room will act to resist creep  
11 closure. However, calculations have shown that because of the high porosity and low stiffness  
12 of the waste and the high waste to potential backfill volume, inclusion of backfill does not  
13 significantly decrease the total subsidence in the waste emplacement area or disposal room  
14 (Westinghouse 1994). Therefore, the **mechanical effects of backfill** have been eliminated  
15 from performance assessment calculations on the basis of low consequence to the  
16 performance of the disposal system.

17  
18 The density of compacted waste is estimated to be around 2,000 kilograms per cubic meter  
19 (Sandia WIPP Project 1992, 2-69) and the grain density of halite in the Salado is  
20 2,163 kilograms per cubic meter (Sandia WIPP Project 1992, Vol. 3, 2-20). It is unlikely that  
21 this density contrast is sufficiently large to overcome drag forces and thus any resultant  
22 **movement of containers** and waste in response to these density contrasts is likely to be  
23 minimal. RH-TRU waste is stored in robust, carbon steel-based containers and will generate  
24 heat through radioactive decay (Section SCR.2.2.2). This heat may induce density changes in  
25 the salt and create buoyancy forces on the containers. Vertical movement of high-level waste  
26 containers of a similar density to those at the WIPP in response to thermally-induced density  
27 changes has been calculated to be around 1 foot (0.35 meters) (Dawson and Tillerson 1978,  
28 22). Containers at the WIPP will generate much less heat, and will therefore move less.  
29 Container movement has therefore been eliminated from performance assessment calculations  
30 on the basis of low consequence to the performance of the disposal system.

31  
32 SCR.2.3.8.2 Repository and Investigation Borehole Seal Performance

33  
34 **Mechanical degradation of seals and consolidation of seals** are accounted for in  
35 performance assessment calculations through the permeability range assumed for the seal  
36 system (Section 6.4.4).

37  
38 There are a large number of boreholes drilled from the surface as part of the site investigation  
39 program for the WIPP. The majority of these **investigation boreholes** do not reach the  
40 repository horizon and terminate in either the Rustler or in the upper part of the Salado. These  
41 shallow boreholes could only act as potential pathways if radionuclides were transported into  
42 the Culebra via the shafts or intrusion boreholes. Three-dimensional groundwater flow  
43 modeling (Corbet 1995) has demonstrated that vertical flow to the Culebra in the controlled  
44 area is downwards and, hence, radionuclides will not migrate up these shallow investigation

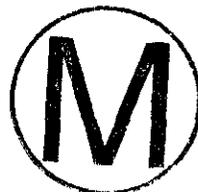

1 boreholes to the accessible environment. There are four WIPP investigation boreholes,  
2 however, that do intersect the repository horizon within the controlled area (ERDA-9,  
3 WIPP-12, WIPP-13, and DOE-1). These could potentially act as pathways to the Culebra or  
4 to the surface for radionuclides that migrate along the anhydrite layers a and b, MB138, and  
5 MB139.

6  
7 WIPP investigation boreholes will be sealed using materials and designs in accord with  
8 industry standards for the Delaware Basin. A survey of plugging practice (Appendix DEL)  
9 shows that the majority of boreholes have a plug below the water-producing zones in the  
10 Rustler and a plug at the top of the Bell Canyon. Drilling and abandonment procedures may  
11 lead to additional plugs within the Salado. A few boreholes (2 percent of those surveyed),  
12 however, have a continuous plug of salt-saturated cement from the top of the Salado to the top  
13 of the Bell Canyon. ERDA-9 will be sealed in a similar manner. Other WIPP investigation  
14 boreholes will be plugged according to regulatory requirements and standard industry practice.  
15 The DOE has committed to plug with cement the portion of these boreholes that penetrate the  
16 Salado.

17  
18 The cement in borehole plugs will react with water that percolates through the plug. If the  
19 plug is confined, as is the case for continuous plugs through the Salado and the Castile, the  
20 greater volume of the alteration phases will cause a decrease in porosity and permeability, a  
21 consequent decrease in the rate of fluid flow through the plug, and hence reduce the rate of  
22 alteration. Some corrosion of the steel casing around the concrete will take place, but the  
23 overall rate of steel corrosion in a closed environment is insufficient to allow an annulus to  
24 form. Salt creep will tend to close any small gaps that do occur in the casing near the base of  
25 the section, further reducing the possibility of brine reaching the concrete plug. Although  
26 localized alteration may take place, the overall permeability of continuous plugs is assumed to  
27 remain equal to or less than the permeability of hardened concrete ( $5 \times 10^{-17}$  square meters) for  
28 10,000 years (Appendix MASS, Section MASS.16.3.2).

29  
30 The cross-sectional area of the WIPP investigation boreholes that penetrate the repository  
31 horizon (typically 0.34 square feet [0.03 square meters] each) is small in comparison to that of  
32 the shafts (which total about 1025.8 square feet [95.3 square meters]). The effective  
33 permeability of the shaft, including the emplaced shaft materials and the DRZ around the  
34 shaft, is comparable to the assumed permeability of investigation boreholes. Transport along  
35 investigation boreholes will, therefore, be of low consequence in comparison to transport  
36 along the shafts, which are explicitly accounted for in performance assessment calculations  
37 (Section SCR.2.1.4 and Section 6.4.4).

38  
39 The design of seals in the investigation boreholes, and the small cross-sectional area of the  
40 boreholes in comparison to the shafts, lead to the conclusion that WIPP investigation  
41 boreholes can be eliminated from performance assessment calculations on the basis of low  
42 consequence to the performance of the disposal system.

1 The site investigation program has also involved the drilling of boreholes from within the  
2 excavated part of the repository. Following their use for monitoring or other purposes, these  
3 **underground boreholes** will be sealed where practical, and salt creep will also serve to  
4 consolidate the seals and to close the boreholes. Any boreholes that remain unsealed will  
5 connect the repository to anhydrite interbeds within the Salado, and thus provide potential  
6 pathways for radionuclide transport. Performance assessment calculations account for fluid  
7 flow to and from the interbeds by assuming that the DRZ has a permanently enhanced  
8 permeability that allows flow of repository brines into specific anhydrite layers and interbeds.  
9 This treatment is also considered to account for the effects of any unsealed boreholes.

10  
11 **SCR.2.4 Subsurface Hydrological and Fluid Dynamic FEPs**

12  
13 **SCR.2.4.1 Repository-Induced Flow**

14  
15 *Two-phase brine and gas flow and capillary rise (wicking) in the repository and the Salado*  
16 *are accounted for in performance assessment calculations.*

17  
18 **Brine inflow** to the repository may occur through the DRZ, impure halite, anhydrite layers, or  
19 clay layers. Pressurization of the repository through gas generation could limit the amount of  
20 brine that flows into the rooms and drifts. Two-phase flow of brine and gas in the repository  
21 and the Salado is accounted for in performance assessment calculations (Section 6.4.3.2).

22  
23 Capillary rise (or **wicking**) is a potential mechanism for liquid migration through unsaturated  
24 zones in the repository. Capillary rise in the waste material could affect gas generation rates,  
25 which are dependent on water availability. Potential releases due to drilling intrusion are also  
26 influenced by brine saturations and therefore by wicking. Capillary rise is therefore accounted  
27 for in performance assessment calculations (Section 6.4.3.2).

28  
29 **SCR.2.4.2 Effects of Gas Generation**

30  
31 *Fluid flow in the repository and Salado due to gas production is accounted for in*  
32 *performance assessment calculations.*

33  
34 Pressurization of the repository through gas generation could limit the amount of brine that  
35 flows into the rooms and drifts. Gas may flow from the repository through the DRZ, impure  
36 halite, anhydrite layers, or clay layers. The amount of water available for reactions and  
37 microbial activity will impact the amounts and types of gases produced (Section SCR.2.5.1).  
38 Gas generation rates, and therefore repository pressure, may change as the water content of the  
39 repository changes. Pressure changes and **fluid flow due to gas production** in the repository  
40 and the Salado are accounted for in performance assessment calculations through modeling  
41 the two-phase flow (Section 6.4.3.2).  
42

1 SCR.2.4.3 Thermal Effects

2  
3 *Convection has been eliminated from performance assessment calculations on the basis of*  
4 *low consequence to the performance of the disposal system.*

5  
6 Temperature differentials in the repository could initiate **convection**. The resulting thermally-  
7 induced brine flow or thermally-induced two-phase flow could influence contaminant  
8 transport. Potentially, thermal gradients in the disposal rooms could drive the movement of  
9 water vapor. For example, temperature increases around waste located at the edges of the  
10 rooms could cause evaporation of water entering from the DRZ. This water vapor could  
11 condense on cooler waste containers in the rooms and could contribute to brine formation,  
12 corrosion, and gas generation.

13  
14 Nuclear criticality (Section SCR.2.2.3), radioactive decay (Section SCR.2.2.2), and  
15 exothermic reactions (Section SCR.2.5.7) are three possible sources of heat in the WIPP  
16 repository.

17  
18 Nuclear criticality has been eliminated from performance assessment calculations on the basis  
19 of low probability of occurrence over 10,000 years (Section SCR.2.2.3).

20  
21 The DOE (1980, 9-149) estimated that radioactive decay of CH-TRU waste will result in a  
22 maximum temperature rise at the center of the repository of 1.6°C at 80 years after waste  
23 emplacement (Section SCR.2.2.2). Sanchez and Trelue (1996) have shown that the total  
24 thermal load of RH-TRU waste will not significantly affect the average temperature increase  
25 in the repository (Section SCR.2.2.2). Temperature increases of about 3°C may occur at the  
26 locations of RH-TRU containers of maximum thermal power (60 watts).

27  
28 Concrete hydration will result in short-term (a few decades) temperature increases in the  
29 vicinity of the concrete seals after emplacement. Loken (1994) and Loken and Chen (1995)  
30 showed that, one week after seal emplacement, concrete hydration could raise the temperature  
31 of the concrete to approximately 53°C and the temperature of the surrounding salt to  
32 approximately 38°C.

33  
34 As discussed in Section SCR.2.5.7.2, the maximum temperature rise in the disposal panels as  
35 a consequence of backfill hydration will be less than 5°C, resulting from brine inflow  
36 following a drilling intrusion into a waste disposal panel. Note that active institutional  
37 controls will prevent drilling within the controlled area for 100 years after disposal. By this  
38 time, any heat generation by radioactive decay and concrete seal hydration will have decreased  
39 substantially, and the temperatures in the disposal panels will have reduced to close to initial  
40 values.

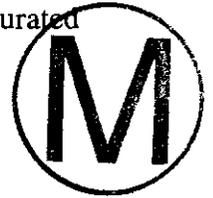

41  
42 Under similar conditions following a drilling event, aluminum corrosion could, at most, result  
43 in a short-lived (two years) temperature increase of about 6°C (see Section SCR.2.5.7.3).  
44 These calculated maximum heat generation rates resulting from aluminum corrosion and

1 backfill hydration could not occur simultaneously because they are limited by brine  
2 availability; each calculation assumes that all available brine is consumed by the reaction of  
3 concern. Thus, the temperature rise of 6°C represents the maximum that could occur as a  
4 result of any combination of exothermic reactions occurring simultaneously.

5  
6 The characteristic velocity,  $V_i$ , for convective flow of fluid component  $i$  in an unsaturated  
7 porous medium is given by (from Hicks 1996);  
8

$$V_i \approx -\frac{k_i}{\mu_i} (\alpha_i \rho_{i0} g \Delta T),$$

9  
10 where  $\alpha_i$  (per degree) is the coefficient of expansion of the  $i^{\text{th}}$  component,  $k_i$  is the intrinsic  
11 permeability (square meters),  $\mu_i$  is the fluid viscosity (pascal second),  $\rho_{i0}$  (kilograms per cubic  
12 meter) is the fluid density at a reference point,  $g$  is the acceleration of gravity, and  $\Delta T$  is the  
13 change in temperature. This velocity may be evaluated for the brine and gas phases expected  
14 in the waste disposal region.

15  
16 For a temperature increase of 10°C, the characteristic velocity for convective flow of brine in  
17 the DRZ around the concrete shaft seals is approximately  $7 \times 10^{-4}$  meters per year ( $2 \times 10^{-11}$   
18 meters per second), and the characteristic velocity for convective flow of gas in the DRZ is  
19 approximately  $1 \times 10^{-3}$  meters per year ( $3 \times 10^{-11}$  meters per second) (Hicks 1996). For a  
20 temperature increase of 25°C, the characteristic velocity for convective flow of brine in the  
21 concrete seals is approximately  $2 \times 10^{-7}$  meters per year ( $6 \times 10^{-15}$  meters per second), and the  
22 characteristic velocity for convective flow of gas in the concrete seals is approximately  $3 \times$   
23  $10^{-7}$  meters per year ( $8 \times 10^{-15}$  meters per second) (Hicks 1996). These values of Darcy  
24 velocity are much smaller than the expected values associated with brine inflow to the  
25 disposal rooms of fluid flow resulting from gas generation. In addition, the buoyancy forces  
26 generated by smaller temperature contrasts in the DRZ, resulting from backfill and concrete  
27 hydration and radioactive decay, will be short-lived and insignificant compared to the other  
28 driving forces for fluid flow. The short-term concrete seals will be designed to function as  
29 barriers to fluid flow for at least 100 years after emplacement, and seal permeability will be  
30 minimized (Wakeley et al. 1995). Thus, temperature increases associated with concrete  
31 hydration will not result in significant buoyancy driven fluid flow through the concrete seal  
32 system. In summary, temperature changes in the disposal system will not cause significant  
33 thermal convection. Furthermore, the induced temperature gradients will be insufficient to  
34 generate water vapor and drive significant moisture migration.

35  
36 Temperature effects on fluid viscosity would be most significant in the DRZ surrounding the  
37 hydrating concrete seals (where temperatures of approximately 38°C are expected). The  
38 viscosity of pure water decreases by about 19 percent over a temperature range of between  
39 27°C and 38°C (Batchelor 1973, 596). Although at a temperature of 27°C, the viscosity of  
40 Salado brine is about twice that of pure water (Rechard et al. 1990, a-19), the magnitude of the  
41 variation in brine viscosity between 27°C and 38°C will be similar to the magnitude of the

1 variation in viscosity of pure water. The viscosity of air over this temperature range varies by  
2 less than 7 percent (Batchelor 1973, 594) and the viscosity of gas in the waste disposal region  
3 over this temperature range is also likely to vary by less than 7 percent. The Darcy fluid flow  
4 velocity for a porous medium is inversely proportional to the fluid viscosity. Thus, increases  
5 in brine and gas flow rates may occur as a result of viscosity variations in the vicinity of the  
6 concrete seals. However, these viscosity variations will persist only for a short period in  
7 which temperatures are elevated, and, thus, the expected variations in brine and gas viscosity  
8 in the waste disposal region will not affect the long-term performance of the disposal system  
9 significantly.

10  
11 In summary, temperature changes in the disposal system will not cause significant thermally-  
12 induced two-phase flow. Thermal convection has been eliminated from performance  
13 assessment calculations on the basis of low consequence to the performance of the disposal  
14 system.

## 15 16 ***SCR.2.5 Geochemical and Chemical FEPs***

### 17 18 ***SCR.2.5.1 Gas Generation***

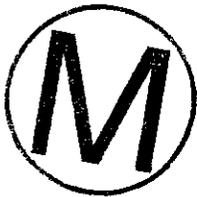

19  
20 Gas generation can affect the mechanical behavior of the host rock and engineered barriers,  
21 chemical conditions, and brine flow, and, as a result, the transport of radionuclides. Potential  
22 gas generation processes include corrosion, microbial degradation, radiolysis, and helium  
23 production.

24  
25 The amount of water available for gas generation will have a major impact on the amounts  
26 and types of gases produced. WIPP waste may contain small amounts of water as residual  
27 liquid; the WAC require that the waste containers have no free liquids. For storage sites with  
28 no capability to repack waste, approval may be given for containers that contain residual  
29 liquids in well-drained containers as long as such residuals do not exceed 1 percent of the  
30 volume of the container. Such residual liquids are expected to be an insignificant source of  
31 liquid in the repository. Water may also be introduced by the influx of brine from the Salado,  
32 as discussed in Section SCR.2.4.1.

33  
34 The following sections discuss gas generation by microbial degradation, corrosion, radiolysis,  
35 and helium production.

#### 36 37 ***SCR.2.5.1.1 Microbial Gas Generation***

38  
39 *Microbial gas generation from degradation of organic material is accounted for in*  
40 *performance assessment calculations, and the effects of temperature and biofilm formation on*  
41 *microbial gas generation are incorporated in the gas generation rates used. The effects of*  
42 *pressure and radiation on microbial gas generation have been eliminated from performance*  
43 *assessment calculations on the basis of low consequence to the performance of the disposal*  
44 *system.*

1 Microbial breakdown of cellulosic material, and possibly plastics and other synthetic  
2 materials, will produce mainly CO<sub>2</sub>, but also N<sub>2</sub>O, N<sub>2</sub>, H<sub>2</sub>S, H<sub>2</sub>, and CH<sub>4</sub>. The rate of  
3 microbial gas production will depend upon the nature of the microbial populations  
4 established, the prevailing conditions, and the substrates present. Microbial gas generation  
5 from **degradation of organic material** is accounted for in performance assessment  
6 calculations.

7  
8 The following subsections discuss the effects of temperature, pressure, radiation, and biofilms  
9 on gas production rates via their control of microbial gas generation processes.

10  
11 *SCR.2.5.1.1.1 Effects of Temperature on Microbial Gas Generation*

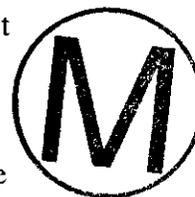

12  
13 Calculations and experimental studies of induced temperature distributions within the  
14 repository have been undertaken and are described in Section SCR.2.2.2. Numerical analysis  
15 suggests that the average temperature increase in the WIPP repository caused by radioactive  
16 decay of the emplaced CH- and RH-TRU waste is likely to be less than 3°C (Section  
17 SCR.2.2.2).

18  
19 Temperature increases resulting from exothermic reactions are discussed in Section  
20 SCR.2.5.7. Potentially the most significant exothermic reactions are concrete hydration,  
21 backfill hydration, and aluminum corrosion. Hydration of the seal concrete could raise the  
22 temperature of the concrete to approximately 53°C and that of the surrounding salt to  
23 approximately 38°C one week after seal emplacement (see Section SCR.2.5.7.1).

24  
25 As discussed in Section SCR.2.5.7.2, the maximum temperature rise in the disposal panels as  
26 a consequence of backfill hydration will be less than 5°C, resulting from brine inflow  
27 following a drilling intrusion into a waste disposal panel. Note that active institutional  
28 controls will prevent drilling within the controlled area for 100 years after disposal. By this  
29 time, any heat generation by radioactive decay and concrete seal hydration will have decreased  
30 substantially, and the temperatures in the disposal panels will have reduced to close to initial  
31 values.

32  
33 Under similar conditions following a drilling event, aluminum corrosion could, at most, result  
34 in a short-lived (two years) temperature rise of about 6°C (see Section SCR.2.5.7.3). These  
35 calculated maximum heat generation rates resulting from aluminum corrosion and backfill  
36 hydration could not occur simultaneously because they are limited by brine availability; each  
37 calculation assumes that all available brine is consumed by the reaction of concern. Thus, the  
38 temperature rise of 6°C represents the maximum that could occur as a result of any  
39 combination of exothermic reactions occurring simultaneously.

40  
41 Relatively few data exist on the **effects of temperature on microbial gas generation** under  
42 expected WIPP conditions. Molecke (1979, 4) summarized microbial gas generation rates  
43 observed during a range of experiments. Increases in temperature from ambient up to 40°C or  
44 50°C were reported to increase gas production, mainly via the degradation of cellulosic waste

1 under either aerobic or anaerobic conditions (Molecke 1979, 7). Above 70°C, however, gas  
2 generation rates were generally observed to decrease. The experiments were conducted over a  
3 range of temperatures and chemical conditions and for different substrates, representing likely  
4 states within the repository. Gas generation rates were presented as ranges with upper and  
5 lower bounds as estimates of uncertainty (Molecke 1979, 7). Later experiments reported by  
6 Francis and Gillow (1994) support the gas generation rate data reported by Molecke (1979).  
7 These experiments investigated microbial gas generation under a wide range of possible  
8 conditions in the repository. These conditions included the presence of microbial inoculum,  
9 humid or inundated conditions, cellulosic substrates, additional nutrients, electron acceptors,  
10 bentonite, and initially oxic or anoxic conditions. These experiments were carried out at a  
11 reference temperature of 30°C, based on the average temperature expected in the repository.  
12 Gas generation rates used in the performance assessment calculations have been derived from  
13 available experimental data and are described in Chapter 6.0 (Section 6.4.3.3). The effects of  
14 temperature on microbial gas generation are implicitly incorporated in the gas generation rates  
15 used.

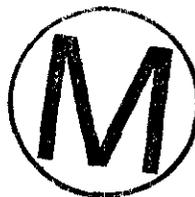

16  
17 *SCR.2.5.1.1.2 Effects of Pressure on Microbial Gas Generation*

18  
19 Chemical reactions may occur depending on, among other things, the concentrations of  
20 available reactants, the presence of catalysts and the accumulation of reaction products, the  
21 biological activity, and the prevailing conditions (for example, temperature and pressure).  
22 Reactions that involve the production or consumption of gases are often particularly  
23 influenced by pressure because of the high molar volume of gases. The effect of high total  
24 pressures on chemical reactions is generally to reduce or limit further gas generation.

25  
26 Few data exist from which the **effects of pressure on microbial gas generation** reactions that  
27 may occur in the WIPP can be assessed and quantified. Studies of microbial activity in deep-  
28 sea environments suggest (for example, Kato et al. 1994, 94) that microbial gas generation  
29 reactions are less likely to be limited by increasing pressures in the disposal rooms than are  
30 inorganic gas generation reactions (for example, corrosion). Consequently, the effects of  
31 pressure on microbial gas generation have been eliminated from performance assessment  
32 calculations on the basis of low consequence to the performance of the disposal system.

33  
34 *SCR.2.5.1.1.3 Effects of Radiation on Microbial Gas Generation*

35  
36 Experiments investigating microbial gas generation rates suggest that the effects of alpha  
37 radiation from TRU waste is not likely to have significant effects on microbial activity  
38 (Barnhart et al. 1980; Francis 1985). Consequently, the **effects of radiation on microbial gas**  
39 **generation** have been eliminated from performance assessment calculations on the basis of  
40 low consequence to the performance of the disposal system.

1 *SCR.2.5.1.1.4 Effects of Biofilms on Microbial Gas Generation*

2  
3 The location of microbial activity within the repository is likely to be controlled by the  
4 availability of substrates and nutrients. Biofilms may develop on surfaces where nutrients are  
5 concentrated. They consist of one or more layers of cells with extracellular polymeric  
6 material and serve to maintain an optimum environment for growth. Within such a biofilm  
7 ecosystem, nutrient retention and recycling maximize microbe numbers on the surface (see,  
8 for example, Stroes-Gascoyne and West 1994, 9 – 10).

9  
10 Biofilms can form on almost any moist surface, but their development is likely to be restricted  
11 in porous materials. Even so, their development is possible at locations throughout the  
12 disposal system. The **effects of biofilms on microbial gas generation** may affect disposal  
13 system performance through control of microbial population size and their effects on  
14 radionuclide transport.

15  
16 Molecke (1979, 4) summarized microbial gas generation rates observed during a range of  
17 experimental studies. The experiments were conducted over a range of temperatures and  
18 chemical conditions and for different substrates representing likely states within the  
19 repository. However, the effect of biofilm formation in these experiments was uncertain.  
20 Molecke (1979, 7), presented gas generation rates as ranges, with upper and lower bounds as  
21 estimates of uncertainty. Later experiments reported by Francis and Gillow (1994) support the  
22 gas generation rate data reported by Molecke (1979). Their experiments investigated  
23 microbial gas generation under a wide range of possible conditions in the repository. These  
24 conditions included the presence of microbial inoculum, humid or inundated conditions,  
25 cellulosic substrates, additional nutrients, electron acceptors, bentonite, and initially oxic or  
26 anoxic conditions. Under the more favorable conditions for microbial growth established  
27 during the experiments, the development of populations of halophilic microbes and associated  
28 biofilms was evidenced by observation of an extracellular, carotenoid pigment,  
29 bacterioruberin, in the culture bottles (Francis and Gillow 1994, 59). Gas generation rates  
30 used in the performance assessment calculations have been derived from available  
31 experimental data and are described in Chapter 6.0 (Section 6.4.3.3). The effects of biofilms  
32 on microbial gas generation rates are implicitly incorporated in the gas generation rates.

33  
34 Biofilms may also influence contaminant transport rates through their capacity to retain and  
35 thus retard both the microbes themselves and radionuclides. This effect is not accounted for  
36 in performance assessment calculations, but is considered potentially beneficial to calculated  
37 disposal system performance. Microbial transport is discussed in Section SCR.2.6.4.

38  
39 *SCR.2.5.1.2 Corrosion*

40  
41 *Gas generation from metal corrosion is accounted for in performance assessment*  
42 *calculations, and the effects of chemical changes from metal corrosion are incorporated in*  
43 *the gas generation rates used. Galvanic coupling between the waste and metals external to*

1 *the repository has been eliminated from performance assessment calculations on the basis of*  
2 *low probability of occurrence over 10,000 years.*

3  
4 Oxidic corrosion of waste drums and metallic waste will occur at early times following closure  
5 of the repository and will deplete its oxygen content. Anoxic corrosion will follow the oxidic  
6 phase and will produce H<sub>2</sub>, while consuming water. **Gases from metal corrosion** are  
7 accounted for in performance assessment calculations.

8  
9 The following subsections discuss the effects on gas production rates of galvanic coupling,  
10 electrochemical gradients, and chemical changes from metal corrosion.

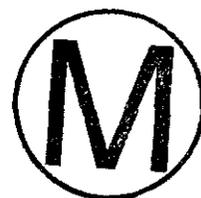

11  
12 *SCR.2.5.1.2.1 Galvanic Coupling and the Effects of Electrochemical Gradients*

13  
14 **Galvanic coupling** refers to the establishment of an electrical current through chemical  
15 processes. Galvanic coupling could lead to the establishment of potential gradients between  
16 metals in the waste form, canisters, and other metals external to the waste form. Such  
17 electrochemical effects can potentially influence corrosion processes and therefore gas  
18 generation rates and chemical migration.

19  
20 Metals other than those in the waste form and canisters could potentially include natural  
21 metallic ore bodies in the host rock and metallic elements in other parts of the repository.  
22 However, the absence of metallic ores in the region (Appendix GCR) allows galvanic  
23 coupling between the waste and metals external to the repository to be eliminated from  
24 performance assessment calculations on the basis of low probability of occurrence over  
25 10,000 years.

26  
27 A variety of metals will be present within the repository (for example, waste metals and  
28 canisters), and the potential exists for galvanic cells to be established over short distances. As  
29 an example, the presence of copper could influence rates of hydrogen gas production resulting  
30 from the corrosion of iron.

31  
32 The precise interactions that may occur are complex and depend on the metals involved, their  
33 physical disposition, and the prevailing conditions (for example, salinity). Good physical and  
34 electrical contact between the metals involved is critical to the establishment of galvanic cells.  
35 Experience with experimental investigations suggests that this condition is unlikely to be  
36 achieved in the repository conditions. In the laboratory, significant efforts are required to  
37 assure metal-to-metal contact sufficient for galvanic coupling to occur. Such contact is  
38 unlikely to occur to a significant extent in the repository. Consequently, given the  
39 preponderance of iron over other metals within the repository and the likely passivation of  
40 many nonferrous materials, the influence of these electrochemical interactions on corrosion,  
41 and therefore gas generation, is expected to be minimal. Therefore, the effects of  
42 electrochemical gradients on gas generation from corrosion have been eliminated from  
43 performance assessment calculations on the basis of low consequence.

1 *SCR.2.5.1.2.2 Effects of Chemical Changes from Metal Corrosion on Gas Generation Rates*

2  
3 The predominant **chemical effect of corrosion** reactions on the environment of disposal  
4 rooms will be to lower the oxidation state of the brines and maintain reducing conditions.

5  
6 Molecke (1979, 4) summarized gas generation rates that were observed during a range of  
7 experiments. The experiments were conducted over a range of temperatures and chemical  
8 conditions representing likely states within the repository. Later experiments reported by  
9 Telander and Westerman (1993) support the gas generation rate data reported by Molecke  
10 (1979). Their experiments investigated gas generation from corrosion under a wide range of  
11 possible conditions in the repository. The studies included corrosion of low-carbon steel  
12 waste packaging materials in synthetic brines, representative of intergranular Salado brines at  
13 the repository horizon, under anoxic (reducing) conditions.

14  
15 Gas generation rates used in the performance assessment calculations have been derived from  
16 available experimental data and are described in Chapter 6.0 (Section 6.4.3.3). The effects of  
17 chemical changes from metal corrosion are, therefore, accounted for in performance  
18 assessment calculations.

19  
20 *SCR.2.5.1.3 Radiolytic Gas Generation*

21  
22 *Gas generation from radiolysis of brine and cellulose, and helium production, have been*  
23 *eliminated from performance assessment calculations on the basis of low consequence to the*  
24 *performance of the disposal system. The formation and transport of radioactive gases has*  
25 *been eliminated from performance assessment calculations on the basis of low consequence to*  
26 *the performance of the disposal system.*

27  
28 This section discusses gas generation resulting from the radiolysis of brine and cellulose,  
29 helium production, and the formation and transport of radioactive gases.

30  
31 *SCR.2.5.1.3.1 Radiolysis of Brine*

32  
33 **Radiolysis of brine** in the WIPP disposal rooms, and of water in the waste, will lead to the  
34 production of gases and may significantly affect the oxygen content of the rooms. This in turn  
35 will affect the prevailing chemical conditions and potentially the concentrations of  
36 radionuclides that may be mobilized in the brines.

37  
38 The overall reaction for the radiolysis of water in the waste and brine is

41  
42 However, the production of intermediate oxygen-bearing species that may subsequently  
43 undergo reduction, such as  $\text{H}_2\text{O}_2$ ,  $\text{ClO}_3^-$ , and  $\text{ClO}_4^-$ , will lead to reduced oxygen gas yields.

1 The remainder of this section is concerned with the physical effects of gas generation by  
 2 radiolysis of brine.

3  
 4 Reed et al. (1993) studied radiolytic gas generation during experiments lasting between 155  
 5 and 182 days. These experiments involved both synthetic brines similar to those sampled  
 6 from the Salado at the WIPP repository horizon, and brines occurring in reservoirs in the  
 7 Castile, as well as real brines sampled from the Salado in the repository workings. The brines  
 8 were spiked with <sup>239</sup>Pu(VI) at concentrations between  $6.9 \times 10^{-9}$  and  $3.4 \times 10^{-4}$  molal. During  
 9 these relatively short-term experiments, hydrogen gas was observed as the product of  
 10 radiolysis. Oxygen gas was not observed; this was attributed to the formation of intermediate  
 11 oxygen-bearing species. However, given sufficient exposure to alpha-emission, oxygen  
 12 production may reach 50 percent that of hydrogen.

13  
 14 An estimate of the potential rate of gas generation due to the radiolysis of brine,  $R_{RAD}$ , can be  
 15 made by making the following assumptions:

- 16 • Gas production occurs following the reaction above, so that 1.5 moles of gas are  
 17 generated for each mole of water consumed.
- 18 • Gas production occurs as a result of the alpha decay of <sup>239</sup>Pu.
- 19 • <sup>239</sup>Pu concentrations in the disposal room brines are controlled by solubility equilibria.
- 20 • All of the dissolved plutonium is <sup>239</sup>Pu.

21  
 22  
 23  
 24  
 25  
 26  $R_{RAD}$  is then given by

$$R_{RAD} = \frac{1.5 \times 3.15 \times 10^7 C_{Pu} Sa_{Pu} \overline{GE}_{\alpha} V_B}{N_D N_A}$$

27  
 28  
 29  
 30 where

- 31
- 32  $R_{RAD}$  = potential rate of gas production (moles per drum per year)
- 33  $C_{Pu}$  = maximum dissolved concentration of plutonium (molal)
- 34  $Sa_{Pu}$  = specific activity of <sup>239</sup>Pu ( $5.42 \times 10^{11}$  becquerels per mole)
- 35  $\overline{E}_{\alpha}$  = average energy of  $\alpha$ -particles emitted during <sup>239</sup>Pu decay ( $5.15 \times 10^6$  electron  
 36 volts)
- 37  $G$  = number of moles of molecules split per 100 eV
- 38  $V_B$  = volume of brine in the repository (liters)
- 39  $N_D$  = number of CH drums in the repository ( $6.7 \times 10^5$ )
- 40  $N_A$  = Avogadro constant ( $6.0 \times 10^{23}$  molecules per mole)
- 41

1 The maximum dissolved concentration of plutonium,  $C_{p_0}$  has been taken as  $3.0 \times 10^{-4}$  molal  
2 based on the dissolved and colloidal actinide source term for the WIPP as described in  
3 Chapter 6.0 (Sections 6.4.3.5 and 6.4.3.6). The value of G used in this calculation has been  
4 set at  $1.5 \times 10^{-2}$ , the upper limit of the range of values observed ( $1.1 \times 10^{-2}$  to  $1.5 \times 10^{-2}$ )  
5 during experimental studies of the effects of radiation on WIPP brines (Reed et al. 1993, 432).  
6 A maximum estimate of the volume of brine that could potentially be present in the disposal  
7 region has been made from its excavated volume (436,000 cubic meters; Sandia WIPP Project  
8 1992, 3-4). This estimate, in particular, is considered to be highly conservative because it  
9 makes no allowance for creep closure of the excavation, or for the volume of waste and  
10 backfill that will be emplaced, and takes no account of factors that may limit brine inflow.  
11 These parameter values lead to an estimate of the potential rate of gas production due to the  
12 radiolysis of brine of 0.6 moles per drum per year.

13  
14 Assuming ideal gas behavior and repository conditions of 30°C and 14.8 megapascals  
15 (lithostatic pressure), this is equivalent to approximately  $6.8 \times 10^4$  liters per year.

16  
17 Potential gas production rates from other processes that will occur in the repository are  
18 significantly greater than this. For example, under water-saturated conditions, microbial  
19 degradation of cellulosic waste has the potential to yield between  $1.3 \times 10^6$  and  $3.8 \times 10^7$  liters  
20 per year; anoxic corrosion of steels has the potential to yield up to  $6.3 \times 10^5$  liters per year  
21 (Chapter 6.0, Section 6.4.3.3).

22  
23 In addition to the assessment of the potential rate of gas generation by radiolysis of brine  
24 given above, a study of the likely consequences on disposal system performance has been  
25 undertaken by Vaughn et al. (1995). A model was implemented in BRAGFLO to estimate  
26 radiolytic gas generation in the disposal region according to the equation above.

27  
28 A set of BRAGFLO simulations was performed to assess the magnitude of the influence of  
29 the radiolysis of brine on contaminant migration to the accessible environment. The  
30 calculations considered radiolysis of H<sub>2</sub>O by 15 isotopes of thorium, plutonium, uranium, and  
31 americium.

32  
33 Conditional complementary cumulative distribution functions (CCDFs) of normalized  
34 contaminated brine releases to the Culebra via a human intrusion borehole and the shaft  
35 system, as well as releases to the subsurface boundary of the accessible environment via the  
36 Salado interbeds, were constructed and compared to the corresponding baseline CCDFs  
37 calculated excluding radiolysis.

38  
39 The comparisons indicated that radiolysis of brine does not significantly affect releases to the  
40 Culebra or the subsurface boundary of the accessible environment under disturbed or  
41 undisturbed conditions (Vaughn et al. 1995). Although the analysis of Vaughn et al. (1995)  
42 used data that are different than those used in the performance assessment calculations,  
43 performance assessment estimates of total gas volumes in the repository are similar to those  
44 considered in the analysis performed by Vaughn et al. (1995).

1 Therefore, gas generation by radiolysis of brine has been eliminated from performance  
2 assessment calculations on the basis of low consequence to the performance of the disposal  
3 system.

4  
5 *SCR.2.5.1.3.2 Radiolysis of Cellulosics*

6  
7 Molecke (1979) compared experimental data on gas production rates caused by **radiolysis of**  
8 **cellulose** and other waste materials with gas generation rates by other processes including  
9 bacterial (microbial) waste degradation. The comparative gas generation rates reported by  
10 Molecke (1979, 4) are given in terms of most probable ranges, using units of moles per year  
11 per drum, for drums of 0.21 cubic meters in volume.

12  
13 A most probable range of 0.005 to 0.011 moles per year per drum is reported for gas  
14 generation due to radiolysis of cellulosic material (Molecke 1979, 4). As a comparison, a  
15 most probable range of 0.0 to 5.5 moles per year per drum is reported for gas generation by  
16 bacterial degradation of waste.

17  
18 The data reported by Molecke (1979) are consistent with more recent gas generation  
19 investigations made under the WIPP program, and indicate that radiolysis of cellulosic  
20 materials will generate significantly less gas than other gas generation processes. Gas  
21 generation from radiolysis of cellulosics therefore can be eliminated from performance  
22 assessment calculations on the basis of low consequence to the performance of the disposal  
23 system.

24  
25 *SCR.2.5.1.3.3 Helium Production*

26  
27 Within the WIPP, **helium gas production** will occur by the reduction of  $\alpha$ -particles (helium  
28 nuclei) emitted from the waste. The maximum amount of helium that could be produced can  
29 be estimated by assuming that all of the  $\alpha$ -particles generated during radioactive decay are  
30 converted to helium gas by the following reaction:

33  
34 The total inventory ( $I$ ) that may be emplaced in the repository is approximately 9 million  
35 curies or  $3.3 \times 10^{17}$  becquerels (see Appendix BIR). Assuming that the inventory continues to  
36 yield  $\alpha$ -particles at this rate throughout the 10,000-year regulatory period (that is, that the  
37 source does not diminish even though the  $\alpha$ -particles are produced during radioactive decay),  
38 the maximum rate of helium gas produced ( $R_{He}$ ) may be calculated from

39  
40 
$$R_{He} = \frac{I}{N_A} ,$$

41  
42 where

1  $R_{He}$  = rate of helium gas production in the repository (mole per second)

2  $I$  = waste inventory ( $3.3 \times 10^{17}$  becquerels)

3  $N_A$  = Avogadro constant ( $6.0 \times 10^{23}$  molecules per mole)

4  
5 These assumptions regarding the inventory lead to maximum estimates for helium production  
6 because, in reality, the total activity will decrease with time and because some of the  
7 radionuclides will decay by beta and gamma emission.

8  
9 Based on the figures and equation given above,  $R_{(He)}$  is approximately  $5.5 \times 10^{-7}$  moles per  
10 second. Assuming ideal gas behavior and repository conditions of 30°C and 14.8  
11 megapascals (lithostatic pressure), this is equivalent to approximately 3.0 liters per year.

12  
13 Gas production rates caused by other processes that will occur in the repository are likely to be  
14 significantly greater than this. For example, under water-saturated conditions, microbial  
15 degradation of cellulosic waste is estimated to yield between  $1.3 \times 10^6$  and  $3.8 \times 10^7$  liters per  
16 year; anoxic corrosion of steels is estimated to yield between 0 and  $6.3 \times 10^5$  liters per year  
17 (Chapter 6.0, Section 6.4, and Appendix MASS). Even if gas production by these processes  
18 were minimal and helium production dominated gas generation, the effects would be of low  
19 consequence because of the low total volumes.

20  
21 Therefore, by estimation of the maximum possible generation rate, the effects of helium  
22 production have been eliminated from performance assessment calculations on the basis of  
23 low consequence to the performance of the disposal system.

24  
25 *SCR.2.5.1.3.4 Radioactive Gases*

26  
27 Based on the composition of the anticipated waste inventory as described in Appendix BIR,  
28 the **radioactive gases** that will be generated in the repository are carbon dioxide (CO<sub>2</sub>) and  
29 methane (CH<sub>4</sub>) containing <sup>14</sup>C, and radon (Rn).

30  
31 Appendix BIR indicates that a small amount of <sup>14</sup>C, 2.88 grams, or 12.85 curies, will be  
32 disposed in the WIPP. This amount is insignificant in comparison with the 40 CFR § 191.13  
33 cumulative release limit for <sup>14</sup>C, estimated to be 525 curies (Appendix BIR).

34  
35 Notwithstanding this comparison, consideration of transport of radioactive gases could  
36 potentially be necessary in respect of the 40 CFR § 191.15 individual protection requirements.  
37 <sup>14</sup>C may partition into carbon dioxide and methane formed during microbial degradation of  
38 cellulosic and other organic wastes (for example, rubbers and plastics). However, total  
39 fugacities of carbon dioxide in the repository are expected to be very low because of the action  
40 of the MgO backfill which will lead to incorporation of carbon dioxide in solid MgCO<sub>3</sub>.  
41 Similarly, interaction of carbon dioxide with cementitious wastes will limit carbon dioxide  
42 fugacities by the formation of solid CaCO<sub>3</sub>. Thus, because of the formation of solid carbonate  
43 phases in the repository, significant transport of <sup>14</sup>C as <sup>14</sup>CO<sub>2</sub> has been eliminated from

1 performance assessment calculations on the basis of low consequence to the performance of  
2 the disposal system.

3  
4 Potentially significant volumes of methane may be produced during the microbial degradation  
5 of cellulosic waste. However, volumes of  $^{14}\text{CH}_4$  will be small given the low total inventory of  
6  $^{14}\text{C}$ , and the tendency of  $^{14}\text{C}$  to be incorporated into solid carbonate phases in the repository.  
7 Therefore, although transport of  $^{14}\text{C}$  could occur as  $^{14}\text{CH}_4$ , this effect has been eliminated from  
8 the current performance assessment calculations on the basis of low consequence to the  
9 performance of the disposal system.

10  
11 Radon gas will contain proportions of the alpha emitters  $^{219}\text{Rn}$ ,  $^{220}\text{Rn}$ , and  $^{222}\text{Rn}$ . All of these  
12 have short half-lives, but  $^{222}\text{Rn}$  is potentially the most important because it is produced from  
13 the abundant waste isotope,  $^{238}\text{Pu}$ , and because it has the longest half-life of the radon isotopes  
14 ( $\approx 4$  days).  $^{222}\text{Rn}$  will exhibit secular equilibrium with its parent  $^{226}\text{Ra}$ , which has a half-life of  
15  $1.6 \times 10^3$  years. Consequently,  $^{222}\text{Rn}$  will be produced throughout the 10,000-year regulatory  
16 time period. Conservative analysis of the potential  $^{222}\text{Rn}$  inventory suggests activities of less  
17 than 716 curies at 10,000 years (Bennett 1996).

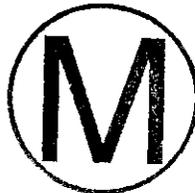

18  
19 Direct comparison of the estimated level of  $^{222}\text{Rn}$  activity with the release limits specified in  
20 40 CFR § 191.13 cannot be made because the release limits do not cover radionuclides with  
21 half-lives less than 20 years. For this reason, production of radon gas can be eliminated from  
22 the performance assessment calculations on regulatory grounds. Notwithstanding this  
23 regulatory argument, the small potential radon inventory means that the formation and  
24 transport of radon gas can also be eliminated from performance assessment calculations on the  
25 basis of low consequence to the performance of the disposal system.

#### 26 27 SCR.2.5.2 Chemical Speciation

28  
29 *Chemical speciation is accounted for in performance assessment calculations in the estimates*  
30 *of radionuclide solubility in the disposal rooms, and the degree of chemical retardation*  
31 *estimated during contaminant transport. The effects of cementitious seals on chemical*  
32 *speciation have been eliminated from performance assessment calculations on the basis of*  
33 *beneficial consequence to the performance of the disposal system. The effects of reaction*  
34 *kinetics in chemical speciation reactions have been eliminated from performance assessment*  
35 *calculations on the basis of low consequence to the performance of the disposal system.*

36  
37 **Chemical speciation** refers to the form in which elements occur under a particular set of  
38 chemical or environmental conditions. Conditions affecting chemical speciation include the  
39 temperature, pressure, and salinity (ionic strength) of the water in question. The importance  
40 of chemical speciation lies in its control of the geochemical reactions likely to occur and the  
41 consequences for actinide mobility.

42  
43 The effects of reaction kinetics in aqueous systems are discussed by Lasaga et al. (1994) who  
44 suggest that in contrast to many heterogeneous reactions, homogeneous aqueous geochemical

1 speciation reactions involving relatively small inorganic species occur rapidly and are  
2 accurately described by thermodynamic equilibrium models that neglect explicit consideration  
3 of reaction kinetics (for example, Lasaga et al. 1994, 2361). Consequently, the **kinetics of**  
4 **speciation** reactions have been eliminated from performance assessment calculation on the  
5 basis of low consequence to the performance of the disposal system.

6  
7 The following subsections discuss chemical speciation in the disposal rooms, shaft seals, and  
8 the Culebra.

9  
10 *SCR.2.5.2.1 Disposal Room*

11  
12 The concentrations of radionuclides that dissolve in any brines present in the disposal rooms  
13 after repository closure will depend on the stability of the chemical species that form under the  
14 prevailing conditions (for example, temperature, pressure, and ionic strength). The method  
15 used to derive radionuclide solubilities in the disposal rooms (see Section 6.4.3.5) considers  
16 the expected conditions. The MgO backfill will buffer pH values in the disposal room to  
17 between 9 and 10. Thus, chemical speciation is accounted for in performance assessment  
18 calculations in the estimates of radionuclide solubility in the disposal rooms.

19  
20 *SCR.2.5.2.2 Repository Seals*

21  
22 Certain repository materials have the potential to interact with groundwater and significantly  
23 alter the chemical speciation of any radionuclides present. In particular, extensive use of  
24 cementitious materials in the seals may have the capacity to buffer groundwaters to extremely  
25 high pH (for example, Bennett et al. 1992, 315 – 325). At high pH values, the speciation and  
26 adsorption behavior of many radionuclides is such that their dissolved concentrations are  
27 reduced in comparison with near-neutral waters. This effect reduces the migration of  
28 radionuclides in dissolved form. The effects of cementitious seals on groundwater chemistry  
29 have been eliminated from performance assessment calculations on the basis of beneficial  
30 consequence to the performance of the disposal system.

31  
32 *SCR.2.5.2.3 Culebra*

33  
34 Chemical speciation will affect actinide retardation in the Culebra. The dependence of  
35 actinide retardation on speciation in the Culebra is accounted for in performance assessment  
36 calculations by sampling over ranges of distribution coefficients ( $K_d$ s). The ranges of  $K_d$ s are  
37 based on the range of groundwater compositions and speciation in the Culebra, including  
38 consideration of nonradionuclide solutes. The methodology used to simulate sorption in the  
39 Culebra is described in Section 6.4.6.2.1.

40  
41 *SCR.2.5.3 Precipitation and Dissolution*

42  
43 *Waste dissolution and the release of radionuclides in the disposal rooms are accounted for in*  
44 *performance assessment calculations. The effect of reaction kinetics in controlling the rate of*

1 waste dissolution within the disposal rooms has been eliminated from performance  
2 assessment calculations on the basis of beneficial consequence to the performance of the  
3 disposal system. The formation of radionuclide bearing precipitates from groundwaters and  
4 brines and the associated retardation of contaminants have been eliminated from  
5 performance assessment calculations on the basis of beneficial consequence to the  
6 performance of the disposal system.

7  
8 **Dissolution of waste and precipitation** of secondary minerals are relevant because of their  
9 control of the concentrations of radionuclides in any brines and groundwaters and the rates of  
10 contaminant transport. Waste dissolution is accounted for in performance assessment  
11 calculations. Mineral dissolution and precipitation processes also have the potential to alter  
12 rock permeabilities and, hence, groundwater flow. Mineral precipitation, for example, may  
13 block pores or fill fractures, resulting in modification of the groundwater flow field.

14  
15 At low temperatures, precipitation and dissolution reactions are caused by changes in fluid  
16 chemistry that result in chemical undersaturation or oversaturation (Bruno and Sandino 1987,  
17 12). Precipitation can be divided into two stages: nucleation and crystal growth. Following  
18 nucleation, growth rates depend on the rates of surface processes and the transport of  
19 materials to the site of growth. The style of mineral dissolution often depends on whether the  
20 rate-controlling process is a surface reaction or is related to the transport of material away  
21 from the site of dissolution. The former case may result in selective dissolution along  
22 crystallographically controlled features, whereas the latter may lead to rapid bulk dissolution  
23 (Berner 1981, 117). Thus, it is expected that a range of kinetic behavior will be exhibited by  
24 different mineral precipitation and dissolution reactions in different geochemical systems.

25  
26 The following subsections discuss dissolution of waste in the disposal rooms and precipitation  
27 in geological units of the WIPP disposal system.

28  
29 *SCR.2.5.3.1 Disposal Room*

30  
31 Waste dissolution in the disposal rooms is accounted for in performance assessment  
32 calculations in the estimates of radionuclide solubility used. The WIPP actinide source term  
33 model is described in detail in Section 6.4.3.5. The assumption of equilibrium waste  
34 dissolution represents a conservative approach to predicting radionuclide concentrations in the  
35 disposal room brines because it yields maximum concentration estimates. The **kinetics of**  
36 **dissolution** within the disposal rooms has been eliminated from performance assessment  
37 calculations on the basis of beneficial consequence to the performance of the disposal system.

38  
39 *SCR.2.5.3.2 Geological Units*

40  
41 During groundwater flow, any radionuclide precipitation processes that occur will lead to  
42 reduced contaminant transport. No credit is given to the potentially beneficial occurrence of  
43 such reactions in performance assessment calculations. The formation of radionuclide-  
44 bearing precipitates from groundwaters and brines and the associated retardation of

1 contaminants has been eliminated from performance assessment calculations on the basis of  
2 beneficial consequence to the performance of the disposal system. The **kinetics of**  
3 **precipitation** reactions have, therefore, also been eliminated from performance assessment  
4 calculations because no credit is taken for precipitation reactions. Dissolution of minerals in  
5 the Culebra and other geological units is discussed in Section SCR.1.1.5.

6  
7 **SCR.2.5.4 Sorption**

8  
9 *Sorption within the disposal rooms, which would serve to reduce radionuclide concentrations,*  
10 *has been eliminated from performance assessment calculations on the basis of beneficial*  
11 *consequence to the performance of the disposal system. The effects of sorption processes in*  
12 *shaft seals and panel closures have been eliminated from performance assessment*  
13 *calculations on the basis of beneficial consequence to the performance of the disposal system.*  
14 *Sorption within the Culebra and the Dewey Lake is accounted for in performance assessment*  
15 *calculations. Sorption processes within other geological units of the disposal system have*  
16 *been eliminated from performance assessment calculations on the basis of beneficial*  
17 *consequence to the performance of the disposal system. Mobile adsorbents (for example,*  
18 *microbes and humic acids), and the sorption of radionuclides at their surfaces, are accounted*  
19 *for in performance assessment calculations in the estimates of the concentrations of actinides*  
20 *that may be carried. The potential effects of reaction kinetics in adsorption processes and of*  
21 *changes in sorptive surfaces are accounted for in performance assessment calculations.*

22  
23 Sorption may be defined as the accumulation of matter at the interface between a solid and an  
24 aqueous solution. Within performance assessment calculations, including those made for the  
25 WIPP, the use of isotherm representations of **actinide sorption** prevails because of their  
26 computational simplicity in comparison with other models (Serne 1992, 238 – 239).

27  
28 The mechanisms that control the **kinetics of sorption** processes are, in general, poorly  
29 understood. Often, sorption of inorganic ions on mineral surfaces is a two-step process  
30 consisting of a short period (typically minutes) of diffusion-controlled, rapid uptake, followed  
31 by slower processes (typically weeks to months) including surface rearrangement, aggregation  
32 and precipitation, and solid solution formation (Davis and Kent 1990, 202). Available data  
33 concerning rates of sorption reactions involving the important radionuclides indicate that, in  
34 general, a range of kinetic behavior is to be expected.

35  
36 The relevance to the WIPP of sorption reaction kinetics lies in their effects on chemical  
37 transport. Sorption of waste contaminants to static surfaces of the disposal system such as  
38 seals and host rocks acts to retard chemical transport. Sorption of waste contaminants to  
39 potentially mobile surfaces, such as colloids, however, may act to enhance chemical transport,  
40 particularly if the kinetics of contaminant desorption are slow or the process is irreversible  
41 (nonequilibrium).

1 The following subsections discuss sorption in the disposal rooms, shaft seals, panel closures,  
2 the Culebra, and other geological units of the WIPP disposal system. Sorption on colloids,  
3 microbes, and particulate material is also discussed.

4  
5 *SCR.2.5.4.1 Disposal Room*

6  
7 The concentrations of radionuclides that dissolve in waters entering the disposal room will be  
8 controlled by a combination of sorption and dissolution reactions. However, because sorption  
9 processes are surface phenomena, the amount of material that is likely to be involved in  
10 sorption mass transfer processes will be small relative to that involved in the bulk dissolution  
11 of waste. WIPP performance assessment calculations therefore assume that dissolution  
12 reactions control radionuclide concentrations. Sorption on waste, containers, and backfill  
13 within the disposal rooms, which would serve to reduce radionuclide concentrations, has been  
14 eliminated from performance assessment calculations on the basis of beneficial consequence  
15 to the performance of the disposal system.

16  
17 *SCR.2.5.4.2 Shaft Seals and Panel Closures*

18  
19 Chapter 3.0 and Appendix SEAL describe the seals that are to be placed at various locations  
20 in the access shafts and waste panel access tunnels. The materials to be used include crushed  
21 salt, bentonite clay, and cementitious grouts. Of these, the latter two in particular possess  
22 significant sorption capacities. No credit is given for the influence of sorption processes that  
23 may occur in seal materials and their likely beneficial effects on radionuclide migration rates.  
24 The effects of sorption processes in shaft seals and panel closures have been eliminated from  
25 performance assessment calculations on the basis of beneficial consequence to the  
26 performance of the disposal system.

27  
28 *SCR.2.5.4.3 Culebra*

29  
30 Sorption within the Culebra is accounted for in performance assessment calculations as  
31 discussed in Section 6.4.6.2. The model used comprises an equilibrium, sorption isotherm  
32 approximation, employing constructed cumulative distribution functions (CDFs) of  
33 distribution coefficients ( $K_d$ s) applicable to dolomite in the Culebra. The potential effects of  
34 reaction kinetics in adsorption processes are encompassed in the ranges of  $K_d$ s used. The  
35 geochemical speciation of the Culebra groundwaters and the effects of **changes in sorptive**  
36 **surfaces** are implicitly accounted for in performance assessment calculations for the WIPP in  
37 the ranges of  $K_d$ s used.

38  
39 *SCR.2.5.4.4 Other Geological Units*

40  
41 During groundwater flow, any radionuclide sorption processes that occur between dissolved  
42 or colloidal actinides and rock surfaces will lead to reduced rates of contaminant transport.  
43 The sorptive capacity of the Dewey Lake is sufficiently large to prevent any radionuclides that  
44 enter it from being released to the accessible environment over 10,000 years (Wallace et al.

1 1995). Thus, sorption within the Dewey Lake is accounted for in performance assessment  
2 calculations as discussed in Section 6.4.6.6. No credit is given to the potentially beneficial  
3 occurrence of sorption in other geological units outside the Culebra. Sorption processes  
4 within other geological units of the disposal system have been eliminated from performance  
5 assessment calculations on the basis of beneficial consequence to the performance of the  
6 disposal system.

7  
8 SCR.2.5.4.5 Sorption on Colloids, Microbes, and Particulate Material

9  
10 The interactions of sorption processes with colloidal, microbial, or particulate transport are  
11 complex. Neglecting sorption of contaminants on immobile surfaces in the repository shafts  
12 and Salado (for example, the clays of the Salado interbeds) is a conservative approach because  
13 it leads to overestimated transport rates. However, neglecting sorption on potentially mobile  
14 adsorbents (for example, microbes and humic acids) cannot be shown to be conservative with  
15 respect to potential releases, because mobile adsorbents may act to transport radionuclides  
16 sorbed to them. Consequently, the concentrations of actinides that may be carried by mobile  
17 adsorbents are accounted for in performance assessment calculations (see Section 6.4.3.6).

18  
19 SCR.2.5.5 Reduction-Oxidation Chemistry

20  
21 *The effects of reduction-oxidation reactions related to metal corrosion on reduction-oxidation*  
22 *conditions are accounted for in performance assessment calculations. Reduction-oxidation*  
23 *reaction kinetics are accounted for in performance assessment calculations. The migration of*  
24 *reduction-oxidation fronts through the repository has been eliminated from performance*  
25 *assessment calculations on the basis of low probability of occurrence over 10,000 years. The*  
26 *formation of localized reducing zones has been eliminated from performance assessment*  
27 *calculations on the basis of low consequence to the performance of the disposal system.*

28  
29 This section considers aspects of the reduction-oxidation chemistry of groundwaters at the  
30 WIPP site.

31  
32 SCR.2.5.5.1 Reduction-Oxidation Kinetics

33  
34 In general, investigation of the reduction-oxidation couples present in aqueous geochemical  
35 systems suggests that most reduction-oxidation reactions are not in thermodynamic  
36 equilibrium (Wolery 1992, 27). The lack of data characterizing the rates of reactions among  
37 trace element reduction-oxidation couples leads to uncertainty in elemental speciation. This  
38 uncertainty in **reduction-oxidation kinetics** is accounted for in performance assessment  
39 calculations in the dissolved actinide source term model (see Section 6.4.3.5), which estimates  
40 the probabilities that particular actinides occur in certain oxidation states.

1 SCR.2.5.5.2 Corrosion

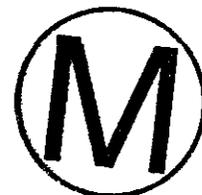

2  
3 Other than gas generation, which is discussed in Section SCR.2.5.1, the main **effect of metal**  
4 **corrosion** will be to influence the chemical conditions that prevail within the repository.  
5 Ferrous metals will be the most abundant metals in the WIPP, and these will corrode on  
6 contact with any brines entering the repository. Initially, corrosion will occur under oxic  
7 conditions owing to the atmospheric oxygen present in the repository at the time of closure.  
8 However, consumption of the available oxygen by corrosion reactions will rapidly lead to  
9 anoxic (reducing) conditions. These changes and controls on conditions within the repository  
10 will affect the chemical speciation of the brines and may affect the oxidation states of the  
11 actinides present. Changes to the oxidation states of the actinides will lead to changes in the  
12 concentrations that may be mobilized during brine flow. The oxidation states of the actinides  
13 are accounted for in performance assessment calculations by the use of parameters that  
14 describe probabilities that the actinides exist in particular oxidation states and, as a result, the  
15 likely actinide concentrations.

16  
17 SCR.2.5.5.3 Reduction-oxidation Fronts

18  
19 The development of **reduction-oxidation fronts** in the disposal system may affect the  
20 chemistry and migration of radionuclides. Reduction-oxidation fronts separate regions that  
21 may be characterized, in broad terms, as having different oxidation potentials. On either side  
22 of a reduction-oxidation front, the behavior of reduction-oxidation-sensitive elements may be  
23 controlled by different geochemical reactions. Elements that exhibit the greatest range of  
24 oxidation states (for example, Pu, U, Np) will potentially be the most affected by reduction-  
25 oxidation front development and migration. The migration of reduction-oxidation fronts may  
26 occur as a result of diffusion processes, or in response to groundwater flow, but will be  
27 restricted by the occurrence of heterogeneous buffering reactions (for example, certain mineral  
28 dissolution and precipitation reactions). Indeed, these buffering reactions cause the typically  
29 sharp, distinct nature of reduction-oxidation fronts.

30  
31 Within the repository, **localized reducing zones**, bounded by reduction-oxidation fronts, may  
32 develop centered on metals undergoing corrosion. However, the formation of such zones  
33 would be of low consequence to disposal system performance owing to the small scale over  
34 which these zones and associated reduction-oxidation fronts could exert an influence on  
35 radionuclide migration. The formation of localized reducing zones has therefore been  
36 eliminated from performance assessment calculations on the basis of low consequence.

37  
38 Of greater significance is the possibility that the flow of fluids having different oxidation  
39 potentials from those established within the repository might lead to the development and  
40 migration of a large-scale reduction-oxidation front. Reduction-oxidation fronts have been  
41 observed in natural systems to be the loci for both the mobilization and concentration of  
42 radionuclides, such as uranium. For example, during investigations at two uranium deposits  
43 at Poços de Caldas, Brazil, uranium was observed by Waber (1991) to be concentrated along  
44 reduction-oxidation fronts at the onset of reducing conditions by its precipitation as  $UO_2$ , the

1 less soluble reduced form, U(IV), of the metal. In contrast, studies of the Alligator Rivers  
2 uranium deposit in Australia by Snelling (1992, 21 – 22) indicated that the movement of the  
3 relatively oxidized weathered zone downwards through the primary ore body as the deposit  
4 was eroded and gradually exhumed led to the formation of secondary uranyl-silicate minerals  
5 and the mobilization of uranium in its more soluble U(VI) form in near-surface waters. The  
6 available geochemical evidence from these sites suggested that the reduction-oxidation fronts  
7 had migrated only slowly, at most on the order of a few tens of meters per million years.  
8 These rates of migration were controlled by a range of factors including the rates of erosion,  
9 infiltration of oxidizing waters, geochemical reactions, and diffusion processes.

10  
11 The migration of large-scale reduction-oxidation fronts through the repository as a result of  
12 regional fluid flow is considered unlikely over the regulatory period on the basis of  
13 comparison with the slow rates of reduction-oxidation front migration suggested by natural  
14 system studies. This comparison is considered conservative because the relatively  
15 impermeable nature of the Salado suggests that reduction-oxidation front migration rates at  
16 the WIPP are likely to be slower than those observed in the more permeable lithologies of the  
17 natural systems studied. Large-scale reduction-oxidation fronts have therefore been  
18 eliminated from performance assessment calculations on the basis of low probability of  
19 occurrence over 10,000 years.

20  
21 SCR.2.5.6 Organic Complexation

22  
23 *The effects of anthropogenic organic complexation reactions, including the effects of organic*  
24 *ligands, have been eliminated from performance assessment calculations on the basis of low*  
25 *consequence to the performance of the disposal system. The presence of humic and fulvic*  
26 *acids is incorporated in performance assessment calculations.*

27  
28 The formation of aqueous complexes between radionuclides and organic materials has the  
29 potential to enhance the total dissolved contaminant load, and thus the potential for  
30 contaminant migration (Tipping 1993, 520). Both naturally occurring and anthropogenic  
31 organic materials may be important and include

- 32  
33 • anthropogenic organics associated with the waste (for example, acetate, citrate,  
34 oxylate, ethylene diamine tetra-acetate [EDTA]), and  
35  
36 • naturally occurring high molecular weight organics, including humin, **humic, and**  
37 **fulvic acids** derived from soil waste.

38  
39 The stability of radionuclide organic complexes is affected by the concentration of  
40 complexants and environmental factors. In general, complexing is favored by increased  
41 concentration of **organic ligands**, increased pH, and decreased ionic strength.

42  
43 In natural systems such as soils, rocks, and groundwaters where many phases and reactive  
44 surfaces exist, individual slow reactions may limit subsequent chemical processes. Biological

1 uptake of radionuclides and other toxic substances may be limited by the rates of complex  
2 dissociation; for certain systems (for example, soils) true equilibrium may never be attained  
3 (for example, Rate et al. 1993, 1408). The limited data that exist concerning the **kinetics of**  
4 **organic complexation** reactions indicate that a range of behavior is to be expected, depending  
5 on the materials involved and the prevailing chemical conditions. For example, studies of the  
6 reactions of certain metals with natural humic materials indicate that desorption rates are  
7 influenced by changes in pH, metal and humic concentration ratio, ionic strength, and absolute  
8 reaction time (Rate et al. 1993, 1414).

9  
10 The basis for eliminating anthropogenic organics from performance assessment calculations is  
11 described in Appendix SOTERM (Section SOTERM.5).

12  
13 The occurrence of humic and fulvic acids is incorporated in performance assessment  
14 calculations in the models for radionuclide transport by humic colloids (see Section 6.4.6.2.2).

15  
16 **SCR.2.5.7 Exothermic Reactions**

17  
18 *The thermal effects of exothermic reactions, including concrete hydration, have been*  
19 *eliminated from performance assessment calculations on the basis of low consequence to the*  
20 *performance of the disposal system.*

21  
22 **Exothermic reactions** liberate heat and will alter the temperature of the disposal system and  
23 affect the properties of the repository and surrounding materials. Dissipation of heat by  
24 conduction through the host rock will act to limit any overall temperature change.

25  
26 Dependent on the amount and rate of energy release, the geometry of the heat source, the  
27 thermal conductivities of the surrounding rocks, and any influence of groundwater or brine  
28 flow on heat transport, these exothermic reactions may lead to elevated temperatures.  
29 Elevated temperatures may influence the rate of salt creep in the surrounding rock, alter the  
30 geochemistry of minerals and waters or brines in the system, and lead to cracking of the seals.

31  
32 In the WIPP, a range of different types of reactions will occur, including corrosion and gas  
33 generation, waste dissolution, and concrete seal and backfill hydration, liberating different  
34 amounts of heat.

35  
36 The amount of heat liberated by the different reactions will depend on the extent of reaction  
37 that occurs and the enthalpy of the reactions themselves. The former will depend on the  
38 inventory of materials emplaced in the WIPP and the subsequent chemical evolution of the  
39 repository system. The latter can be assessed by considering typical enthalpies for the reaction  
40 types of interest.

41  
42 Even though there is uncertainty surrounding the extent of reactions that will occur,  
43 consideration of typical reaction enthalpies suggests that the concrete and backfill hydration  
44 reactions have the greatest potential to evolve significant amounts of heat (Bennett et al.

1996). The effects of these processes on the WIPP are discussed further below. By contrast, the thermal effects of waste dissolution and gas generation by corrosion will be of low consequence. Potential heat generation from nuclear criticality is discussed in Section SCR.2.2.3 and heat generation from radioactive decay is discussed in Section SCR.2.2.2.

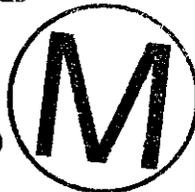

*SCR.2.5.7.1 Elevated Temperatures as a Result of Concrete Hydration*

Elevated temperatures in the concrete seals may influence the rate of salt creep in the surrounding rock, alter the geochemistry of minerals and waters or brines in the system, and lead to cracking of the seals.

**Concrete hydration** reactions are known to proceed for extended periods (perhaps thousands of years); however, the rates of these reactions decrease with time and, within the WIPP, the greatest evolution of heat will occur during the short period following seal emplacement and repository closure. A quantitative analysis of the thermal effects of emplacing large concrete seals in salt at the WIPP was made by Loken (1994) and Loken and Chen (1995). The analysis suggests that the energy released by the hydration of the seal concrete could raise the temperature of the concrete to approximately 53° C, and that of the surrounding salt to approximately 38°C, one week after seal emplacement. Loken (1994) and Loken and Chen (1995) also examined the potential for cracking of the seals in response to short-term stresses that could develop as a result of thermal expansion of the concrete and long-term stresses caused by creep of the surrounding salt. At both time scales, radially compressive, horizontal stresses are likely to develop in the concrete due to the presence of the surrounding salt. The magnitude of these stresses caused by short-term thermal pulse was calculated to be less than 9.2 megapascals, well below the design compressive strength of the concrete (which for SMC is 31 megapascals). Maximum long-term stresses will develop in the deepest parts of the seals where lithostatic pressure is greatest (14.8 megapascals). Again, these are well below the design compressive strength of the concrete (31 megapascals). Loken's (1994) and Loken and Chen's (1995) analyses also considered potential vertical stresses in the concrete seals. The magnitude of these stresses depends on the thermal history of the seal and the weight of overburden present. The calculations indicated that 50 years after seal emplacement the thermal changes in the seals could lead to maximum tensile stresses of approximately 3 megapascals. Even for the shallowest parts of the shaft seal system, these stresses will be less than the weight of the overburden (6.0 megapascals), making tensile cracking of the seals unlikely.

Thus, Loken's (1994) and Loken and Chen's (1995) analyses confirm that any temperature changes associated with concrete hydration will occur at early times (at most some decades) after repository closure and suggest that significant cracking of the seals will be unlikely. The effects of any minor thermal cracking of concrete seals on seal permeability are accounted for in performance assessment calculations via the range of seal permeabilities used.

WIPP waste contains cement that is used to solidify liquids, particulates, and sludges. All the waste to be emplaced at the WIPP will contain a total of about  $8.5 \times 10^6$  kilograms of cement

(Bennett et al. 1996). This is equivalent to about  $1.5 \times 10^7$  moles of CaO per waste disposal panel, representing the cement as CaO. Although a substantial amount of hydration may occur prior to waste disposal, this process will continue at a slower rate after disposal. Concrete hydration can be described by the reaction

Disregarding the hydration that will occur prior to disposal and assuming a brine inflow rate of 200 cubic meters per year (the maximum calculated rate, which occurs for the scenario involving an E1 drilling event at 350 years after disposal), the reaction rate of concrete hydration in the panel will be about  $1.1 \times 10^7$  moles per year, and the reaction could continue for about 1.4 years. Concrete hydration in the waste will generate a thermal load of about 23 kilowatts, based on a reaction enthalpy of -65 kilojoules per mole. Bennett et al. (1996) estimated that the maximum temperature that could be generated by concrete hydration of the waste within a panel is about 2°C. Such a temperature rise will have an insignificant effect on the performance of the disposal system, as discussed further in Sections SCR.2.3.7 (thermally-induced stress), SCR.2.4.3 (thermal convection), SCR.2.5.1.1 (gas generation), and SCR.2.7.3 (thermochemical transport).

The potential effects of elevated temperatures on chemical reactions in the seals and surrounding regions include increased actinide solubilities and alteration of mineral assemblages leading to altered sorption characteristics. Despite the potential for such effects to occur, the short duration of the thermal pulse caused by concrete hydration is such that it will not significantly affect actinide transport in the long term. Sorption within the seals has been eliminated from performance assessment calculations on the basis of beneficial consequence to the performance of the disposal system. Consequently, changes to the sorption characteristics of the seals can also be eliminated from performance assessment calculations.

Thus, the effects of exothermic concrete hydration reactions have been eliminated from performance assessment calculations on the basis of low consequence to the performance of the disposal system.

#### SCR.2.5.7.2 Elevated Temperatures as a Result of Backfill Hydration

The potential for the development of elevated temperatures in the repository as a result of exothermic backfill hydration reactions has been assessed by Bennett et al. (1996). In their analysis, Bennett et al. (1996) made the following assumptions:

- Hydration of the backfill can be described by the reaction

- Reaction will proceed rapidly so that the rate of heat generation will be controlled by the rate of brine inflow to the repository.
- Reaction will occur uniformly throughout the repository so that all brine entering will contact and react with backfill.
- All of the backfill emplaced will undergo hydration.

The maximum calculated rate of brine inflow into a panel (about 200 cubic meters per year) occurs for the scenario involving an E1 drilling event at 350 years after disposal. The molar density of water is  $5.56 \times 10^4$  moles per cubic meter and thus the reaction rate of backfill hydration in the panel will be  $1.1 \times 10^7$  moles per year. Backfill hydration will generate a thermal load of about 13 kilowatts, based on a reaction enthalpy of 38 kilojoules per mole. There will be about  $2 \times 10^8$  moles MgO emplaced per panel and thus the reaction could continue for about 20 years if sufficient brine was available. Bennett et al. (1996) estimated the maximum temperature that could be generated by backfill hydration within a panel for such a thermal load. Assuming heat loss will occur by conduction through the salt forming the roof and floor of the panel and that heat losses through the side walls are negligible, the maximum temperature rise in a panel, as a consequence of backfill hydration would be less than 5°C. This magnitude of temperature rise will have an insignificant effect on the performance of the disposal system, as discussed further in Sections SCR.2.3.7 (thermally-induced stress), SCR.2.4.3 (thermal convection), SCR.2.5.1.1 (gas generation), and SCR.2.7.3 (thermochemical transport).

The potential effects of elevated temperatures on chemical reactions in the disposal rooms and surrounding regions include increased actinide solubilities and alteration of mineral assemblages leading to altered sorption characteristics. Despite the potential for such effects to occur, the small temperature rise caused by backfill hydration is such that it will not significantly affect the chemical behavior of the actinides beyond the range of uncertainty considered in estimation of the actinide source term (Section 6.4.3.5). Sorption within the backfill has been eliminated from performance assessment calculations on the basis of beneficial consequence to the performance of the disposal system. Consequently, changes to the sorption characteristics of the backfill can also be eliminated from performance assessment calculations.

Thus, the effects of exothermic backfill hydration reactions have been eliminated from performance assessment calculations on the basis of low consequence to the performance of the disposal system.

#### SCR.2.5.7.3 Elevated Temperatures as a Result of Other Exothermic Reactions

Bennett et al. (1996) also considered the potential effects on temperature of a number of other exothermic reactions in the repository. These included backfill carbonation, microbial degradation, and aluminum corrosion.

1 Backfill carbonation will be limited by microbial CO<sub>2</sub> production; the maximum rate of CO<sub>2</sub>  
2 production is expected to be 2.9 × 10<sup>5</sup> moles per year. Backfill carbonation can be described  
3 by the reaction

4  
5  
6  
7 Backfill carbonation will generate a thermal load of about 0.7 kilowatts, based on a reaction  
8 enthalpy of -77 kilojoules per mole. About 3.6 × 10<sup>7</sup> moles CO<sub>2</sub> could be produced in a  
9 single panel and thus the reaction could continue for about 125 years. Bennett et al. (1996)  
10 estimated the maximum temperature that could be generated by backfill carbonation within a  
11 panel to be about 0.6°C.

12  
13 The maximum reaction rate for microbial degradation in a panel will be about 1 × 10<sup>5</sup> moles  
14 per year and the inventory is about 1.2 × 10<sup>7</sup> moles C<sub>6</sub>H<sub>10</sub>O<sub>5</sub> per panel. Microbial degradation  
15 can be described by the reaction

16  
17  
18  
19 This reaction could continue for about 120 years. Microbial degradation will generate a  
20 thermal load of about 1 kilowatt, based on a reaction enthalpy of -312 kilojoules per mole.  
21 Bennett et al. (1996) estimated the maximum temperature that could be generated by  
22 microbial degradation within a panel to be about 0.8°C. Aluminum corrosion can be  
23 described by the reaction

24  
25  
26  
27 Thus, the rate of corrosion of aluminum will be controlled by brine availability. The reaction  
28 rate of aluminum corrosion in the panel will be about 0.4 × 10<sup>7</sup> moles per year, assuming a  
29 brine inflow rate of 200 cubic meters per year (1.1 × 10<sup>7</sup> moles per year). This rate of brine  
30 inflow represents the maximum calculated rate, which occurs for the scenario involving an E1  
31 drilling event at 350 years after disposal. About 8 × 10<sup>6</sup> moles of aluminum will be emplaced  
32 in each panel and thus aluminum corrosion could continue for two years.

33  
34 Aluminum corrosion will generate a thermal load of about 51 kilowatts for a reaction enthalpy  
35 of -434 kilojoules per mole. Bennett et al. (1996) estimated the maximum temperature that  
36 could be generated by aluminum corrosion within a panel to be about 6°C.

37  
38 These calculated temperature rises resulting from backfill carbonation, microbial degradation,  
39 and aluminum corrosion will not have a significant effect on the performance of the disposal  
40 system, as discussed further in Sections SCR.2.3.7 (thermally-induced stress), SCR.2.4.3  
41 (thermal convection), SCR.2.5.1.1 (gas generation), and SCR.2.7.3 (thermochemical  
42 transport).

1 SCR.2.5.8 Chemical Effects on Material Properties

2  
3 *The effects of chemical degradation of seals and of microbial growth on concrete are*  
4 *accounted for in performance assessment calculations. The effects on material properties of*  
5 *the chemical degradation of backfill have been eliminated from performance assessment*  
6 *calculations on the basis of low consequence.*

7  
8 The concrete used in the seal systems will degrade due to chemical reaction with the  
9 infiltrating groundwater. Degradation could lead to an increase in permeability of the seal  
10 system. The main uncertainties with regard to cement degradation rates at the WIPP are the  
11 effects of groundwater chemistry, the exact nature of the cementitious phases present, and the  
12 rates of brine infiltration. The performance assessment calculations take a conservative  
13 approach to these uncertainties by assuming a large increase in permeability of the concrete  
14 seals only a few hundred years after closure. These permeability values are based on seal  
15 design considerations and consider the potential effects of degradation processes. Therefore,  
16 the effects of **chemical degradation of seals** are accounted for in performance assessment  
17 calculations through the CDFs used for seal material permeabilities.

18  
19 Concrete can be inhabited by alkalophilic bacteria which could produce acids thereby  
20 accelerating the seal degradation process. Nitrification processes, which will produce nitric  
21 acid, tend to be aerobic, and will be further limited at the WIPP by the low availability of  
22 ammonium in the brines (Pedersen and Karlsson 1995, 75). Because of the limitations on  
23 growth because of the chemical conditions, it is likely that the effects of **microbial growth on**  
24 **concrete** will be small. The effects of such microbial activity on seal properties are, therefore,  
25 implicitly accounted for in performance assessment calculations through the CDFs used for  
26 seal material permeabilities.

27  
28 Degradation of the chemical conditioners or backfill added to the disposal room is a  
29 prerequisite of their function in buffering the chemical environment of the disposal room  
30 (Section SCR.2.5.2). However, the chemical reactions and dissolution involved will change  
31 the physical properties of the material. Because the mechanical and hydraulic characteristics  
32 of the backfill have been eliminated from performance assessment calculations on the basis of  
33 low consequence to the performance of the disposal system, the effects of the **chemical**  
34 **degradation of backfill** on material properties have been eliminated from performance  
35 assessment calculations on the same basis.

36  
37 **SCR.2.6 Contaminant Transport Mode FEPs**

38  
39 Following waste emplacement brine may contact the waste and radionuclides will dissolve.  
40 Radionuclide mobility will be affected by radionuclide speciation, solubility, sorption, and  
41 precipitation. Chemical and microbial decomposition of organics in the waste may result in  
42 the transport of some radionuclides as organic complexes, colloids, and particulate material.  
43 Radionuclides bound to microbes might also be transported. Potentially, radionuclides will

1 migrate with the brine by advection and diffusion through the repository, seals, the DRZ, and  
2 pores and fractures in the rock matrix.

3  
4 The following subsections discuss briefly the transport of radionuclides in a number of  
5 different forms: fully dissolved, colloidal, particulate, bound to microbes, and combined with  
6 gas.

7  
8 **SCR.2.6.1 Solute Transport**

9  
10 *Transport of dissolved radionuclides is accounted for in performance assessment*  
11 *calculations.*

12  
13 **Solute transport** may occur by advection, dispersion, and diffusion down chemical potential  
14 gradients, and is accounted for in performance assessment calculations (Sections 6.4.5.4 and  
15 6.4.6.2.1).

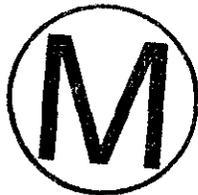

16  
17 **SCR.2.6.2 Colloid Transport**

18  
19 *Formation of colloids, transport of colloidal radionuclides, and colloid retardation through*  
20 *filtration and sorption are accounted for in performance assessment calculations.*

21  
22 Colloids typically have sizes of between 1 nanometer and 1 micrometer and may form stable  
23 dispersions in groundwaters. **Colloid formation and stability** depends on their composition  
24 and the prevailing chemical conditions (for example, salinity). Depending on their size,  
25 **colloid transport** may occur at different rates than those of fully dissolved species. They may  
26 be physically excluded from fine porous media, and their migration may be accelerated  
27 through fractured media in channels where velocities are greatest. However, they can also  
28 interact with the host rocks during transport and become retarded. These interactions may be  
29 of a chemical or physical nature and include electrostatic effects, leading to **colloid sorption**,  
30 and sieving leading to **colloid filtration** and pore blocking. Colloid formation and stability is  
31 accounted for in performance assessment calculations through estimates of colloid numbers in  
32 the disposal room based on the prevailing chemical conditions (Section 6.4.3.6). Colloid  
33 sorption, filtration, and transport in the Culebra are accounted for in performance assessment  
34 calculations (Section 6.4.6.2.2).

35  
36 **SCR.2.6.3 Particulate Transport**

37  
38 *The formation of particulates through rinse and subsequent transport of radionuclides in*  
39 *groundwater and brine has been eliminated from performance assessment calculations for*  
40 *undisturbed conditions on the basis of low consequence to the performance of the disposal*  
41 *system. The transport of radionuclides as particulates (cuttings, cavings, and spillings)*  
42 *during penetration of the repository by a borehole, is accounted for in performance*  
43 *assessment calculations.*  
44

1 **Suspensions of particles** having sizes above the colloidal range are, by definition, unstable  
2 because they are subject to gravitational settling. Within the WIPP disposal rooms (the only  
3 potential source of active particulates), it is unlikely that brine flow will be rapid enough to  
4 generate (through **rinse**) and transport particulate suspensions under undisturbed conditions.  
5 Mobilization of any suspensions that may form would have the effect of a local and minor  
6 redistribution of radionuclides within the room and is unlikely, therefore, to result in  
7 significantly increased radionuclide transport from the repository. The formation of  
8 particulates through rinse and subsequent transport of radionuclides in groundwater and brine  
9 has therefore been eliminated from performance assessment calculations for undisturbed  
10 conditions on the basis of low consequence to the performance of the disposal system.

11  
12 Inadvertent human intrusion into the repository by a borehole could result in transport of  
13 waste material to the ground surface through drilling-induced flow and blowouts (Section  
14 SCR.3.2.1.1.2). This waste could include material intersected by the drill bit (**cuttings**),  
15 material eroded from the borehole wall by circulating drilling fluid (**cavings**), and material  
16 that enters the borehole as the repository depressurizes (**spallings**). Transport of radionuclides  
17 by these materials and in brine is accounted for in performance assessment calculations and is  
18 discussed in Section 6.4.7.1.

19  
20 **SCR.2.6.4 Microbial Transport**

21  
22 *Transport of radionuclides bound to microbes is accounted for in performance assessment*  
23 *calculations. The effects of biofilms on microbial transport have been eliminated from*  
24 *performance assessment calculations on the basis of beneficial consequence to the*  
25 *performance of the disposal system.*

26  
27 Microbes will be introduced into the disposal rooms during the operational phase of the  
28 repository and will also occur naturally in geological units throughout the disposal system.  
29 Because of their colloidal size, microbes, and any radionuclides bound to them, may be  
30 transported at different rates than radionuclides in solution. **Microbial transport** of  
31 radionuclides is accounted for in performance assessment calculations (Section 6.4.6.2.2).

32  
33 **Biofilms** (see Section SCR.2.5.1) may influence microbial and radionuclide transport rates  
34 through their capacity to retain, and therefore retard, both the microbes themselves and  
35 radionuclides. This effect has been eliminated from performance assessment calculations on  
36 the basis of beneficial consequence to the performance of the disposal system.

37  
38 **SCR.2.6.5 Gas Transport**

39  
40 *The transport of radioactive gases has been eliminated from performance assessment*  
41 *calculations on the basis of low consequence to the performance of the disposal system.*  
42

1 The production and potential **transport of radioactive gases** is discussed in Section  
2 SCR.2.5.1.3, where they are eliminated from performance assessment calculations on the  
3 basis of low consequence to the performance of the disposal system.

4  
5 **SCR.2.7 Contaminant Transport Processes**

6  
7 **SCR.2.7.1 Advection**

8  
9 *Advection of contaminants is accounted for in performance assessment calculations.*

10  
11 **Advection** (that is, the transport of dissolved and solid material by flowing fluid) is accounted  
12 for in performance assessment calculations (Sections 6.4.5.4 and 6.4.6.2).

13  
14 **SCR.2.7.2 Diffusion**

15  
16 *Diffusion of contaminants and retardation by matrix diffusion are accounted for in*  
17 *performance assessment calculations.*

18  
19 **Diffusion** (that is, the movement of molecules or particles both parallel to and transverse to  
20 the direction of advection in response to Brownian forces) and, more specifically **matrix**  
21 **diffusion**, whereby movement is transverse to the direction of advection within a fracture and  
22 into the surrounding rock matrix, are accounted for in performance assessment calculations  
23 (Section 6.4.6.2).

24  
25 **SCR.2.7.3 Thermochemical Transport Phenomena**

26  
27 *The effects of thermochemical transport phenomena (the Soret effect) have been eliminated*  
28 *from performance assessment calculations on the basis of low consequence to the*  
29 *performance of the disposal system.*

30  
31 According to Fick's law, the diffusion flux of a solute is proportional to the solute gradient.  
32 In the presence of a temperature gradient there will also be a solute flux proportional to the  
33 temperature gradient (the **Soret effect**). Thus, the total solute flux **J** in a liquid phase may be  
34 expressed as

35  
36 
$$\mathbf{J} = - D\nabla C - ND\nabla T ,$$

37  
38 where C is the solute concentration, T is the temperature of the liquid, D is the solute  
39 diffusion coefficient, and

40 
$$N = S_T C(1-C) ,$$

41  
42 in which  $S_T$  is the Soret coefficient. The mass conservation equation for solute diffusion in a  
43 liquid is then

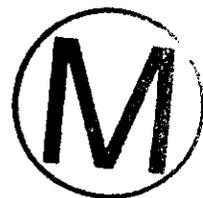

$$\frac{\partial C}{\partial t} = \nabla \cdot (D \nabla C + N D \nabla T) .$$

In liquids having both light and heavy molecules, the heavier molecules tend to concentrate in the colder regions in the presence of a temperature gradient. Typically, large temperature gradients are required for Soret diffusion to be significant compared to Fickian diffusion.

Radioactive decay, nuclear criticality, and exothermic reactions are three possible sources of heat in the WIPP repository. The DOE (1980, 9-149) estimated that radioactive decay of CH-TRU waste will result in a maximum temperature rise at the center of the repository of 1.6°C at 80 years after waste emplacement (Section SCR.2.2.2). Sanchez and Trelue (1996) have shown that the total thermal load of RH-TRU waste will not significantly affect the average temperature increase in the repository. Temperature increases of about 3°C may occur at the locations of RH-TRU containers of maximum thermal power (60 watts). Such temperature increases are likely to be short-lived because of the rapid decay of heat-producing nuclides in RH-TRU waste, such as <sup>137</sup>Cs, <sup>90</sup>Sr, <sup>241</sup>Pu, and <sup>147</sup>Pm, whose half-lives are approximately 30, 29, 14, and 3 years, respectively. Soret diffusion generated by such temperature contrasts will be negligible compared to other radionuclide transport mechanisms.

Nuclear criticality is eliminated from performance assessment calculations on the basis of low probability of occurrence over 10,000 years (Section SCR.2.2.3).

Temperature increases resulting from exothermic reactions are discussed in Section SCR.2.5.7. Potentially the most significant exothermic reactions are concrete hydration, backfill hydration, and aluminum corrosion. Hydration of the seal concrete could raise the temperature of the concrete to approximately 53°C and that of the surrounding salt to approximately 38°C one week after seal emplacement (see Section SCR.2.5.7.1). However, the concrete seals will be designed to function as barriers to fluid flow for at least 100 years after emplacement, and seal permeability will be minimized (Wakeley et al. 1995). Thus, short-term temperature increases associated with concrete hydration will not result in significant Soret diffusion through the seal system.

As discussed in Section SCR.2.5.7.2, the maximum temperature rise in the disposal panels as a consequence of backfill hydration will be less than 5°C, resulting from brine inflow following a drilling intrusion into a waste disposal panel. Note that active institutional controls will prevent drilling within the controlled area for 100 years after disposal. By this time, any heat generation by radioactive decay and concrete seal hydration will have decreased substantially, and the temperatures in the disposal panels will have reduced to close to initial values.

Under similar conditions following a drilling intrusion, aluminum corrosion could, at most, result in a short-lived (two years) temperature increase of about 6°C (see Section SCR.2.5.7.3). These calculated maximum heat generation rates resulting from aluminum corrosion and backfill hydration could not occur simultaneously because they are limited by

1 brine availability; each calculation assumes that all available brine is consumed by the  
2 reaction of concern. Thus, the temperature rise of 6°C represents the maximum that could  
3 occur as a result of any combination of exothermic reactions occurring simultaneously.  
4 Temperature increases of this magnitude will not result in significant Soret diffusion within  
5 the disposal system.

6  
7 In summary, the limited magnitude and spatial scale of temperature gradients in the disposal  
8 system indicate that Soret diffusion will be insignificant. Thus, the effects of thermochemical  
9 transport phenomena have been eliminated from performance assessment calculations on the  
10 basis of low consequence to the performance of the disposal system.

#### 11 12 SCR.2.7.4 Electrochemical Transport Phenomena

13  
14 *The effects of electrochemical transport phenomena, comprising electrochemical reactions*  
15 *and electrophoresis, have been eliminated from performance assessment calculations on the*  
16 *basis of low consequence to the performance of the disposal system. The effects of galvanic*  
17 *coupling between the waste and metals external to the repository on transport have been*  
18 *eliminated from performance assessment calculations on the basis of low probability of*  
19 *occurrence over 10,000 years.*

20  
21 This section discusses electrochemical transport phenomena, including galvanic coupling,  
22 electrochemical reactions, and electrophoretic effects.

23  
24 Potential gradients may exist in the subsurface as a result of groundwater flow and  
25 electrochemical reactions. The development of such potentials may be associated with the  
26 weathering of sulfide ore bodies, variations in rock properties at geological contacts,  
27 bioelectric activity associated with organic matter, natural corrosion reactions, and  
28 temperature and pressure gradients in groundwaters. With the exception of mineralization  
29 potentials associated with metallic sulfide ores (see below), the magnitude of such potentials  
30 is usually less than about 100 millivolts and the potentials tend to average to zero over  
31 distances of several thousand feet (Telford et al. 1976, 458). Temporary currents may be  
32 induced over larger distances by activity in the ionosphere, thunderstorms, and nuclear blasts.  
33 The short duration and spasmodic nature of these **electrochemical effects** is such that they  
34 have been eliminated from performance assessment calculations on the basis of low  
35 consequence to the performance of the disposal system.

36  
37 With regard to the WIPP, **galvanic coupling** refers to the establishment of electrical potential  
38 gradients between metals in the waste form, canisters, and other metals external to the waste  
39 form. Such electrochemical effects can potentially influence corrosion processes, gas  
40 generation rates, and chemical migration. Metals other than those in the waste form and  
41 canisters can potentially include natural metallic ore bodies in the host rock and metallic  
42 elements emplaced in other parts of the repository. The absence of metallic sulfide ores in the  
43 region (Appendix GCR) allows galvanic coupling between the waste and metals external to

1 the repository to be eliminated from performance assessment calculations on the basis of low  
2 probability of occurrences over 10,000 years.

3  
4 A variety of metals will be present within the repository (for example, waste metals and metal  
5 packaging), and cells can be established over short distances. The precise interactions that  
6 may occur are complex and depend on the metals involved, their physical characteristics, and  
7 the prevailing conditions. Good physical and electrical contact between the metals involved is  
8 critical to the establishment of galvanic cells. Experiments suggest that good electrical  
9 contact is not likely to be established under repository conditions (Telander and Westerman  
10 1993). Consequently, given the preponderance of iron over other metals within the repository  
11 and the likely passivation of many nonferrous materials, the influence of these interactions on  
12 corrosion reactions and gas generation have been eliminated from performance assessment  
13 calculations on the basis of low consequence. Because electrochemical cells that may be  
14 established are small, the effect of such cells on the migration of contaminants (for example,  
15 by **electrophoresis**) has also been eliminated from performance assessment calculations on  
16 the basis of low consequence to the performance of the disposal system.

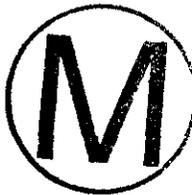

17  
18 SCR.2.7.5 Physicochemical Transport Phenomena

19  
20 *The effects of alpha-recoil processes on radionuclide transport have been eliminated from*  
21 *performance assessment calculations on the basis of low consequence to performance of the*  
22 *disposal system. The effects of enhanced diffusion across chemical gradients have been*  
23 *eliminated from performance assessments on the basis of low consequence to the performance*  
24 *of the disposal system. The effects of chemical gradients between material boundaries are*  
25 *accounted for in performance assessment calculations through the treatment of mineral*  
26 *fragment colloids (Section 6.4). The effects of osmotic processes have been eliminated from*  
27 *performance assessment calculations on the basis of beneficial consequence to the*  
28 *performance of the disposal system.*

29  
30 Physicochemical transport phenomena discussed in this section are associated with alpha-  
31 recoil and chemical gradients. These processes have the potential to influence the transport of  
32 contaminants throughout the disposal system.

33  
34 SCR.2.7.5.1 Alpha Recoil

35  
36 During decay of certain radionuclides, alpha particles may be emitted with sufficiently high  
37 energies that the daughter nuclide recoils appreciably to conserve system momentum. An  
38 example is the decay of a  $^{238}\text{U}$  atom (originally at rest) to  $^{234}\text{Th}$  with the emission of an alpha  
39 particle. In this case, the alpha particle is ejected with a considerable kinetic energy  
40 (approximately 4.1 megaelectron volts [ $6.57 \times 10^{-13}$  joules]). Following the law of  
41 conservation of linear momentum, the daughter nuclide,  $^{234}\text{Th}$ , recoils with an energy of  
42 approximately 0.07 megaelectron volts ( $1.12 \times 10^{-14}$  joules). The potential relevance of these  
43 alpha-recoil processes to disposal system performance lies in the energy imparted to the  $^{234}\text{Th}$   
44 nuclide. The energy is great enough to cause the  $^{234}\text{Th}$  nuclide to move a short distance

1 through a crystal lattice (for example uraninite). If it is close enough to the surface of the  
2 crystal, it will be ejected into the surrounding groundwater or transferred to an adjoining solid  
3 phase.

4  
5  $^{234}\text{Th}$  decays rapidly to  $^{234}\text{Pa}$  and subsequently to  $^{234}\text{U}$ . The half-lives of these subsequent  
6 decay processes are 24.1 days and 1.17 minutes, respectively. Thus, in combination, these  
7 recoil and decay processes can lead to the apparent preferential dissolution or leaching of  $^{234}\text{U}$   
8 relative to  $^{238}\text{U}$  from crystal structures and amorphous or adsorbed phases. This preferential  
9 leaching may also be enhanced by the radiation damage to the host phase during the emission  
10 of the alpha particle. Consequently,  $^{234}\text{U}$  may exhibit different transport behavior than  $^{238}\text{U}$   
11 and contribute differently to any calculated risk.

12  
13 The potential influence of **alpha-recoil** processes on radionuclide transport through natural  
14 geologic media is dependent on many site-specific factors. Among these factors are the  
15 mineralogy, geometry, and microstructure of the rocks, as well as geometrical constraints on  
16 the type of groundwater flow (for example, porous or fracture flow). Studies of natural  
17 radionuclide-bearing groundwater systems often fail to discern any measurable effect of alpha-  
18 recoil processes on radionuclide transport above the background uncertainty introduced by the  
19 spatial heterogeneity of the geological system under consideration. Consequently, the effects  
20 of the alpha-recoil processes that occur on radionuclide transport are thought to be minor.  
21 These effects have therefore been eliminated from performance assessment calculations on the  
22 basis of low consequence to the performance of the disposal system.

#### 23 SCR.2.7.5.2 Chemical Gradients

24  
25  
26 The existence of **chemical gradients** within the disposal system, induced naturally or  
27 resulting from repository material and waste emplacement, may influence the transport of  
28 contaminants in several ways. Such gradients may exist at the interfaces between different  
29 repository materials and between repository and geological materials. For example, distinct  
30 chemical regimes are likely to be established within the concrete seals and the adjoining host  
31 rocks. Similarly, chemical gradients will exist between the waste and chemical conditioners  
32 and the surrounding rocks of the Salado. Other chemical gradients may exist as a result of the  
33 juxtaposition of relatively dilute groundwaters and brines or between groundwaters with  
34 different chemistries. Natural gradients currently exist between different groundwaters in the  
35 Culebra.

36  
37 A possible consequence of chemical gradients that occur at material boundaries is the  
38 **enhanced diffusion** of materials. However, it is likely that the length scales over which such  
39 enhanced diffusion might occur will be small in comparison to the scale of the disposal  
40 system. Furthermore, a significant amount of diffusion across such interfaces will tend to  
41 reduce the driving force for migration. Therefore, the effects of enhanced diffusion across  
42 chemical gradients at material boundaries have been eliminated from performance  
43 assessments on the basis of low consequence to the performance of the disposal system.

1 Other processes may be induced by the existence of chemical gradients at material boundaries,  
2 including the formation or destabilization of colloids. For example, cementitious materials  
3 will be emplaced in the WIPP as part of the waste and in the seals. Cementitious materials  
4 contain colloidal-sized phases, such as calcium-silicate-hydrate gels, and alkaline pore fluids.  
5 Chemical gradients will exist between the pore fluids in the cementitious materials and their  
6 less alkaline surroundings. Chemical interactions at these interfaces may lead to the  
7 generation of colloids by chemical precipitation, and these colloids could potentially play a  
8 role in actinide transport.

9  
10 The chemical conditions that will develop in the cements are such that any colloids generated  
11 from them will be of the inorganic, mineral fragment type. Candidate colloidal compositions  
12 include calcium and magnesium oxides, calcium hydroxide, calcium-aluminum silicates,  
13 calcium-silicate-hydrate gels, and silica. Experimental investigations of the stability of  
14 inorganic, mineral fragment type colloidal dispersions have been carried out as part of the  
15 WIPP colloid-facilitated actinide transport program (Papenguth and Behl 1996, 83 – 84).  
16 These investigations indicate that the salinities of the brines at WIPP are sufficient to cause  
17 kinetic destabilization of mineral fragment type colloidal dispersions. Therefore,  
18 concentrations of any colloids generated from concrete within the repository are expected to  
19 be extremely low. These concentrations are considered in performance assessment  
20 calculations.

21  
22 The existence of distinct interfaces between waters of different salinities (and therefore  
23 different densities) may limit the mixing of the water bodies and affect flow and contaminant  
24 transport. Such effects have been eliminated from performance assessment calculations on  
25 the basis of low consequence to the performance of the disposal system.

26  
27 Under appropriate circumstances, **osmotic processes** may occur at interfaces between waters  
28 of different salinities. Osmosis is the process by which water (or any other solvent) diffuses  
29 through a semipermeable (or differentially permeable) membrane in response to a  
30 concentration gradient. In geologic settings, osmotic processes can occur if waters of different  
31 salinities and/or chemistries exist on either side of a particular lithology (for example, clay) or  
32 a lithological boundary that behaves as a semipermeable membrane. At the WIPP, clay layers  
33 within the Salado may act as semipermeable membranes across which osmotic processes may  
34 occur.

35  
36 In the absence of hydrological gradients across a semipermeable membrane, water will move  
37 by osmosis from the more dilute water into the more saline water. However, because of the  
38 nature of the membrane, the migration of dissolved contaminants across the interface may be  
39 restricted. The existence of a hydrological gradient across a semipermeable membrane may  
40 enhance or oppose water movement by osmosis, depending on its direction and magnitude. In  
41 cases where advection dominates over osmosis and reverse osmosis occurs, dissolved  
42 contaminants that cannot pass through the semipermeable membrane may be advected  
43 towards the membrane and concentrated along the interface. Thus, both osmosis and reverse  
44 osmosis can restrict the migration of dissolved contaminants and possibly lead to their

1 concentration along interfaces between different water bodies. The effects of osmotic  
2 processes have been eliminated from performance assessment calculations on the basis of  
3 beneficial consequence to the performance of the disposal system.

4  
5 **SCR.2.8 Ecological FEPs**

6  
7 **SCR.2.8.1 Plant, Animal, and Soil Uptake**

8  
9 *Plant uptake, animal uptake, and accumulation in soils have been eliminated from compliance*  
10 *assessment calculations for 40 CFR § 191.15 on the basis of low consequence. Plant uptake*  
11 *and animal uptake in the accessible environment have been eliminated from performance*  
12 *assessment calculations for 40 CFR § 191.13 on regulatory grounds. Accumulation in soils*  
13 *within the controlled area has been eliminated from performance assessment calculations for*  
14 *40 CFR § 191.13 on the basis of beneficial consequence.*

15  
16 The results of the calculations presented in Section 6.5 show that releases to the accessible  
17 environment under undisturbed conditions are restricted to lateral releases through the DRZ at  
18 repository depth. Thus, for evaluating compliance with the EPA's individual protection  
19 requirements in 40 CFR § 191.15, FEPs that relate to **plant uptake, animal uptake, and**  
20 **accumulation in soils** have been eliminated from compliance assessment calculations on the  
21 basis of low consequence.

22  
23 Performance assessments for evaluating compliance with the EPA's cumulative release  
24 requirements in 40 CFR § 191.13 need not consider radionuclide migration in the accessible  
25 environment. Therefore, FEPs that relate to plant uptake and animal uptake in the accessible  
26 environment have been eliminated from performance assessment calculations on regulatory  
27 grounds. Accumulation in soils that may occur within the controlled area would reduce  
28 releases to the accessible environment and can, therefore, be eliminated from performance  
29 assessment calculations on the basis of beneficial consequence.

30  
31 **SCR.2.8.2 Human Uptake**

32  
33 *Ingestion, inhalation, irradiation, dermal sorption, and injection have been eliminated from*  
34 *compliance assessment calculations for 40 CFR § 191.15 and Subpart C of 40 CFR Part 191*  
35 *on the basis of low consequence. FEPs that relate to human uptake in the accessible*  
36 *environment has been eliminated from performance assessment calculations for 40 CFR*  
37 *§ 191.13 on regulatory grounds.*

38  
39 As described in Section 8.1.1, releases to the accessible environment under undisturbed  
40 conditions are restricted to lateral migration through anhydrite interbeds within the Salado.  
41 Because of the bounding approach taken for evaluating compliance with the EPA's individual  
42 protection requirements in 40 CFR § 191.15 and the groundwater protection requirements in  
43 Subpart C of 40 CFR Part 191 (see Chapter 8.0, Sections 8.1.2.2 and 8.2.3), FEPs that relate

1 to human uptake by **ingestion, inhalation, irradiation, dermal sorption, and injection** have  
2 been eliminated from compliance assessment calculations on the basis of low consequence.

3  
4 Performance assessments for evaluating compliance with the EPA's cumulative release  
5 requirements in 40 CFR § 191.13 need not consider radionuclide migration in the accessible  
6 environment. Therefore, FEPs that relate to human uptake in the accessible environment have  
7 been eliminated from performance assessment calculations on regulatory grounds.

### 8 9 **SCR.3 Human-Initiated EPs**

10  
11 The human-initiated EPs discussed in this section are relevant to the analyses conducted to  
12 determine compliance with the Containment Requirements in 40 CFR § 191.13, the Individual  
13 Protection Requirements in 40 CFR § 191.15, and the Environmental Standards for Ground  
14 Water Protection in Subpart C of 40 CFR Part 191. The DOE's consideration of human-  
15 initiated EPs draws on the criteria provided in 40 CFR Part 194 for certification of the WIPP's  
16 compliance with the 40 CFR Part 191 disposal regulations.

17  
18 In Section SCR.3.1, the DOE discusses the requirements in 40 CFR Part 191 and criteria in  
19 40 CFR Part 194 concerning the consideration of human-initiated EPs in compliance  
20 applications. In the remainder of Section SCR.3, the DOE discusses human-initiated EPs in  
21 the context of the FEP categorization scheme presented in Table SCR-3: the human-initiated  
22 EPs presented in Table SCR-3 are highlighted in the text of the screening discussions. The  
23 geology category (SCR.3.2) is concerned with human activities that could disrupt the  
24 subsurface structure. The hydrology and geochemistry category (SCR.3.3) is concerned with  
25 the potential effects of disruptive human activities on subsurface fluid flow and chemistry.  
26 The categories concerned with geomorphology (SCR.3.4), surface hydrology (SCR.3.5),  
27 climate (SCR.3.6), marine environment (SCR.3.7), and ecology (SCR.3.8) relate to potential  
28 effects on the disposal system of human-initiated EPs occurring at or near the land surface.

#### 29 30 ***SCR.3.1 Regulatory Requirements***

31  
32 Regulatory requirements on FEPs represent FEP screening decisions made by the EPA. Thus,  
33 the logic and rationale for regulatory screening decisions are based on one or both of the  
34 following:

- 35  
36 • Exclusion by the EPA in language that forms part of the 40 CFR Part 191 standard.
- 37  
38 • Exclusion by the EPA in language that forms part of the 40 CFR Part 194 criteria.

39  
40 Regulatory screening arguments are used largely to limit speculation concerning future,  
41 potentially disruptive, human-initiated EPs. In particular, the criterion in 40 CFR § 194.25(a),  
42 concerned with predictions of the future states of society, requires that compliance

**Legend:**

- UP FEPs accounted for in the assessment calculations for undisturbed performance for 40 CFR § 191.13 (as well as 40 CFR § 191.15 and Subpart C of 40 CFR Part 191).
- DP FEPs accounted for (in addition to all UP FEPs) in the assessment calculations for disturbed performance for 40 CFR § 191.13.
- SO-R FEPs eliminated from performance assessment calculations on the basis of regulations provided in 40 CFR Part 191 and criteria provided in 40 CFR Part 194.
- SO-C FEPs eliminated from performance assessment (and compliance assessment) calculations on the basis of consequence.
- SO-P FEPs eliminated from performance assessment (and compliance assessment) calculations on the basis of low probability of occurrence.

assessments and performance assessments<sup>3</sup> “shall assume that characteristics of the future remain what they are at the time the compliance application is prepared.” The scope of compliance assessments and performance assessments, with respect to the consideration of human-initiated EPs, is discussed in the following subsections.

<sup>3</sup> The analyses conducted to determine compliance with 40 CFR §191.15 and Subpart C of 40 CFR Part 191 are defined in 40 CFR §194.2 as “compliance assessments.” “Performance assessments” (defined in 40 CFR §191.12) are required to determine compliance with the Containment Requirements in 40 CFR §191.13.

1 SCR.3.1.1 Scope of Compliance Assessments

2  
3 Compliance assessments need only consider the undisturbed performance of the disposal  
4 system (as stated in 40 CFR § 191.15(a) and 40 CFR § 191.24(a)(1)). “Undisturbed  
5 performance” is defined in 40 CFR § 191.12 as “...the predicted behavior of a disposal system,  
6 including consideration of the uncertainties in predicted behavior, if the disposal system is not  
7 disrupted by human intrusion or the occurrence of unlikely natural events.” The scope of  
8 compliance assessments is clarified further with respect to human-initiated EPs in 40 CFR  
9 § 194.54(b), which states that

10  
11 Compliance assessments of undisturbed performance shall include the effects on the disposal  
12 system of: (1) Existing boreholes in the vicinity of the disposal system, with attention to the  
13 pathways they provide for migration of radionuclides from the site; and (2) Any activities that  
14 occur in the vicinity of the disposal system prior to or soon after disposal. Such activities shall  
15 include, but shall not be limited to: Existing boreholes and the development of any existing  
16 leases that can be reasonably expected to be developed in the near future, including boreholes  
17 and leases that may be used for fluid injection activities.  
18

19 The DOE assumes that “the vicinity of the disposal system” is a region outside and adjacent to  
20 the controlled area that extends far enough to include any activities that can affect the disposal  
21 system. Assessments of undisturbed performance must include consideration of human-  
22 initiated EPs relating to activities that have taken place or are reasonably expected to take  
23 place in the vicinity of the disposal system in the near future.  
24

25 SCR.3.1.2 Scope of Performance Assessments

26  
27 Assessments of compliance with the Containment Requirements in 40 CFR § 191.13 require  
28 consideration of “all significant processes and events,” including human-initiated EPs. The  
29 scope of performance assessments is clarified with respect to human-initiated EPs in 40 CFR  
30 § 194.32. At 40 CFR § 194.32(a) the EPA states that

31  
32 Performance assessments shall consider natural processes and events, mining, deep drilling,  
33 and shallow drilling that may affect the disposal system during the regulatory time frame.  
34

35 Thus, performance assessments must include consideration of human-initiated EPs relating to  
36 mining and drilling activities that might take place during the regulatory time frame. In  
37 particular, performance assessments must consider the potential effects of such activities that  
38 might take place within the controlled area at a time when institutional controls cannot be  
39 assumed to eliminate completely the possibility of human intrusion.  
40

41 In implementing the Assurance Requirements (40 CFR § 191.14), the EPA has provided  
42 criteria relating to the effectiveness of institutional controls. With respect to active  
43 institutional controls, 40 CFR § 194.41(b) states that

44  
45 Performance assessments shall not consider any contributions from active institutional controls  
46 for more than 100 years after disposal.

1  
2 The DOE assumes credit for active institutional controls, such that no human intrusion will  
3 take place within the controlled area for 100 years after disposal. However, consistent with  
4 40 CFR § 194.41(b), the DOE assumes no credit in performance assessments for active  
5 institutional controls for more than 100 years after disposal.

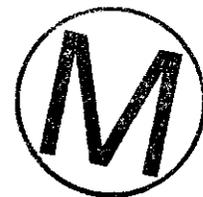

6  
7 Criteria concerning the credit that can be used for passive institutional controls in reducing the  
8 likelihood of future human intrusion are provided in 40 CFR § 194.43(c):  
9

10 The Administrator may allow the Department to assume passive institutional control credit, in  
11 the form of reduced likelihood of human intrusion, if the Department demonstrates in the  
12 compliance application that such credit is justified because the passive institutional controls are  
13 expected to endure and be understood by potential intruders for the time period approved by  
14 the Administrator. Such credit, or a smaller credit as determined by the Administrator, cannot  
15 be used for more than several hundred years and may decrease over time. In no case, however,  
16 shall passive institutional controls be assumed to eliminate the likelihood of human intrusion  
17 entirely.  
18

19 The preamble to 40 CFR Part 194 clarifies that in performance assessments “the likelihood of  
20 mining may be decreased by passive institutional controls and active institutional controls, to  
21 the extent that can be justified in the compliance application and to a degree identical to that  
22 assumed for drilling.” The preamble also limits any credit for passive institutional controls in  
23 deterring human intrusion to 700 years after disposal. For performance assessment  
24 calculations, passive institutional controls are assumed to be 99 percent effective for the  
25 period of time from 100 years to 700 years after disposal, as discussed in Section 6.4.12.1.  
26 Thus, the rates of future drilling and mining for the duration of this 600-year period are  
27 assumed to be 1 percent of the predicted rates of drilling and mining after 700 years.  
28

29 Further criteria concerning the scope of performance assessments are provided at 40 CFR  
30 § 194.32(c):  
31

32 Performance assessments shall include an analysis of the effects on the disposal system of any  
33 activities that occur in the vicinity of the disposal system prior to disposal and are expected to  
34 occur in the vicinity of the disposal system soon after disposal. Such activities shall include,  
35 but shall not be limited to, existing boreholes and the development of any existing leases that  
36 can be reasonably expected to be developed in the near future, including boreholes and leases  
37 that may be used for fluid injection activities.  
38

39 Performance assessments must include consideration of all human-initiated EPs relating to  
40 activities that have taken place or are reasonably expected to take place in the vicinity of the  
41 disposal system in the near future.  
42

#### 43 SCR.3.1.3 Categorization of Human Activities

44

45 In order to implement the criteria in 40 CFR Part 194 relating to the scope of compliance  
46 assessments and performance assessments, three categories of human activities have been  
47 defined. Distinctions are made between (1) human activities that are currently taking place

1 and those that took place prior to the time of the compliance application, (2) human activities  
2 that might be initiated in the near future after submission of the compliance application, and  
3 (3) human activities that might be initiated after repository closure. The first two categories of  
4 EPs are considered under undisturbed performance, and EPs in the third category lead to  
5 disturbed performance conditions.

6  
7 *SCR.3.1.3.1 Historical, Current, and Near-Future Human Activities*

8  
9 Historical and current human activities include all types of resource extraction activities that  
10 have historically taken place and are currently taking place outside the controlled area. These  
11 activities are of potential significance insofar as they could affect the geological, hydrological,  
12 or geochemical characteristics of the disposal system or groundwater flow pathways outside  
13 the disposal system. Current human activities taking place within the controlled area are  
14 essentially those associated with development of the WIPP repository, which are considered in  
15 Section SCR.2. The observational data obtained as part of WIPP site characterization reflect  
16 any effects of historical and current human activities in the vicinity of the WIPP, such as  
17 groundwater extraction and oil and gas production. However, such human activities have  
18 resulted only in minor disturbances to the hydrological and geochemical conditions within the  
19 controlled area, that will have no significant effects on the long-term performance of the  
20 disposal system.

21  
22 Near-future human activities include resource extraction activities that may be expected to  
23 occur outside the controlled area based on existing plans and leases. Such activities are of  
24 potential significance insofar as they could affect the geological, hydrological, or geochemical  
25 characteristics of the disposal system or groundwater flow pathways outside the disposal  
26 system. The only human activities that are expected to occur within the controlled area in the  
27 near future are those associated with development of the WIPP repository, which are  
28 considered in Section SCR.2. In order to bound the analysis of the effects of human activities  
29 outside the controlled area, the DOE assumes that any activity that is expected to be initiated  
30 in the near future, based on existing plans and leases, will be initiated prior to repository  
31 closure. Activities initiated prior to repository closure are assumed to continue until their  
32 completion, potentially at some time after disposal.

33  
34 Compliance assessments (in order to satisfy the criteria in 40 CFR § 194.54(b)) and  
35 performance assessments (in order to satisfy the criteria in 40 CFR § 194.32(c)) must consider  
36 the potential effects of historical, current, and near-future human activities on the performance  
37 of the disposal system. Historical, current, and near-future human-initiated EPs and their  
38 screening classification are summarized in Table SCR-3.

39  
40 *SCR.3.1.3.2 Future Human Activities*

41  
42 Future human activities include activities that might be initiated within or outside the  
43 controlled area after repository closure. Performance assessments, but not compliance  
44 assessments, must consider the effects of future human activities on the performance of the

1 disposal system. The EPA has provided criteria relating to future human activities in 40 CFR  
2 § 194.32(a), which limit the scope of consideration of future human activities in performance  
3 assessments to mining and drilling. Mining and drilling could occur within the disposal  
4 system at a time when institutional controls cannot be assumed to eliminate completely the  
5 possibility of such activities. Thus, mining and drilling may occur within the controlled area  
6 after the end of the period of active institutional control (100 years after disposal). Future  
7 human activities could potentially influence the transport of contaminants within and outside  
8 the disposal system, by resulting in direct removal of waste from the disposal system or  
9 alteration of the geological, hydrological, or geochemical characteristics of the disposal  
10 system. Future human-initiated EPs and their screening classification are summarized in  
11 Table SCR-3.

12  
13 *SCR.3.1.3.2.1 Criteria Concerning Future Mining*

14  
15 The EPA provides additional criteria concerning the type of future mining that should be  
16 considered by the DOE in 40 CFR § 194.32(b):

17  
18       Assessments of mining effects may be limited to changes in the hydraulic conductivity of the  
19 hydrogeologic units of the disposal system from excavation mining for natural resources.  
20 Mining shall be assumed to occur with a one in 100 probability in each century of the  
21 regulatory time frame. Performance assessments shall assume that mineral deposits of those  
22 resources, similar in quality and type to those resources currently extracted from the Delaware  
23 Basin, will be completely removed from the controlled area during the century in which such  
24 mining is randomly calculated to occur. Complete removal of such mineral resources shall be  
25 assumed to occur only once during the regulatory time frame.

26  
27 Thus, consideration of future mining may be limited to mining within the disposal system at  
28 the locations of resources that are similar in quality and type to those currently extracted from  
29 the Delaware Basin.

30  
31 *SCR.3.1.3.2.2 Criteria Concerning Future Drilling*

32  
33 With respect to consideration of future drilling, in the preamble to 40 CFR Part 194, the EPA  
34 “reasoned that while the resources drilled for today may not be the same as those drilled for in  
35 the future, the present rates at which these boreholes are drilled can nonetheless provide an  
36 estimate of the future rate at which boreholes will be drilled.” Criteria concerning the  
37 consideration of future deep and shallow drilling<sup>4</sup> in performance assessments are provided in  
38 40 CFR § 194.33. These criteria state that, to calculate future drilling rates, the DOE should  
39 examine the historical rate of drilling for resources in the Delaware Basin. Historical drilling  
40 for purposes other than resource recovery (such as WIPP site investigation) need not be  
41 considered in determining future drilling rates.

---

<sup>4</sup> In 40 CFR §194.2, deep drilling is defined as “drilling events in the Delaware Basin that reach or exceed a depth of 2,150 feet below the surface relative to where such drilling occurs” and shallow drilling is defined as “drilling events in the Delaware Basin that do not reach a depth of 2,150 feet below the surface relative to where such drilling occurred.”

**Title 40 CFR Part 191 Compliance Certification Application**

---

1 In particular, in calculating the frequency of future deep drilling, 40 CFR § 194.33(b)(3)(i)  
2 states that the DOE should

3  
4 Identify deep drilling that has occurred for each resource in the Delaware Basin over the past  
5 100 years prior to the time at which a compliance application is prepared.  
6

7 and, in calculating the frequency of future shallow drilling, 40 CFR § 194.33(b)(4)(i) requires  
8 that the DOE should

9  
10 Identify shallow drilling that has occurred for each resource in the Delaware Basin over the  
11 past 100 years prior to the time at which a compliance application is prepared.  
12

13 An additional criterion with respect to the calculation of future shallow drilling rates is  
14 provided in 40 CFR § 194.33(b)(4)(iii):

15  
16 In considering the historical rate of all shallow drilling, the Department may, if justified,  
17 consider only the historical rate of shallow drilling for resources of similar type and quality to  
18 those in the controlled area.  
19

20 As an example of the use of the criterion in 40 CFR § 194.33(b)(4)(iii), the EPA states in the  
21 Supplementary Information to 40 CFR Part 194 that “if only non-potable water can be found  
22 within the controlled area, then the rate of drilling for water may be set equal to the historical  
23 rate of drilling for non-potable water in the Delaware Basin over the past 100 years.” Thus,  
24 the DOE may estimate the rate of future shallow drilling within the controlled area based on a  
25 determination of the potential resources in the controlled area.  
26

27 The EPA also provides criteria in 40 CFR § 194.33(d) concerning the use of future boreholes  
28 subsequent to drilling:

29  
30 With respect to future drilling events, performance assessments need not analyze the effects of  
31 techniques used for resource recovery subsequent to the drilling of the borehole.  
32

33 Thus, performance assessments need not consider the effects of techniques used for resource  
34 extraction and recovery that would occur subsequent to the drilling of a future borehole.  
35

36 The EPA provides additional criteria that limit the severity of human intrusion scenarios that  
37 must be considered in performance assessments. In 40 CFR § 194.33(b)(1), the EPA states  
38 that

39  
40 Inadvertent and intermittent intrusion by drilling for resources (other than those resources  
41 provided by the waste in the disposal system or engineered barriers designed to isolate such  
42 waste) is the most severe human intrusion scenario.  
43

44 Thus, human intrusion scenarios involving intentional intrusion into the WIPP excavation, for  
45 example, to recover resources, need not be considered in performance assessments.  
46

1 *SCR.3.1.3.3 Summary of Regulatory Requirements*

2  
3 Analyses of undisturbed performance of the disposal system, included in compliance  
4 assessments and performance assessments, must consider the potential effects of historical,  
5 current, and near-future human activities. For the analyses of undisturbed performance, it is  
6 assumed that the human-initiated EPs that can be eliminated from performance assessment  
7 calculations on the basis of low probability of occurrence, low consequence, or beneficial  
8 consequence can be eliminated from compliance assessment calculations on similar bases.

9  
10 Performance assessments must also include consideration of future human activities that  
11 could lead to disturbed performance conditions, although the scope of consideration of future  
12 human activities is limited to mining and drilling. In the following sections, in order to  
13 distinguish between undisturbed performance and disturbed performance, separate screening  
14 discussions and screening decisions are presented for historical, current, and near-future  
15 human-initiated EPs, and for future human-initiated EPs.

16  
17 *SCR.3.2 Geological EPs*

18  
19 The human activities discussed in this section are those that could disrupt the geology of the  
20 disposal system, or the geology in the vicinity of the disposal system, resulting in or  
21 modifying subsurface pathways for fluid flow. Drilling, excavation activities, and subsurface  
22 explosions could create interconnections between hydraulically conductive horizons, alter  
23 hydrogeological or geochemical characteristics of the disposal system, or result in direct  
24 transport of radionuclides to the accessible environment. In this section, the types of  
25 geological activities that need to be considered with regard to potential consequences are  
26 defined; the subsurface hydrological and geochemical effects of these activities are considered  
27 in Section SCR.3.3.

28  
29 *SCR.3.2.1 Drilling*

30  
31 *Drilling associated with geothermal energy production, liquid waste disposal, hydrocarbon*  
32 *storage, archeology, and deliberate intrusion into the excavated repository, has been*  
33 *eliminated from performance assessment calculations on regulatory grounds. The effects of*  
34 *historical, current, and near-future drilling associated with water resources exploration,*  
35 *groundwater exploitation, potash exploration, oil and gas exploration, oil and gas*  
36 *exploitation, enhanced oil and gas recovery, and drilling to explore other resources, has been*  
37 *eliminated from performance assessment calculations on the basis of low consequence to the*  
38 *performance of the disposal system (Section SCR.3.3.1). Historical shallow drilling*  
39 *associated with water resources exploration, potash exploration, and groundwater*  
40 *exploitation, is accounted for in calculations to determine the rate of future shallow drilling.*  
41 *Historical deep drilling associated with oil and gas exploration, oil and gas exploitation,*  
42 *enhanced oil and gas recovery, potash exploration, and exploration for other resources*  
43 *(sulfur) is accounted for in calculations to determine the rate of future deep drilling.*  
44

1 This section discusses historical, current, and near-future drilling activities within and outside  
2 the controlled area and drilling activities that may take place within or outside the controlled  
3 area in the future. Drilling may occur within the controlled area in the future after the end of  
4 the period of active institutional control (100 years after disposal). Section SCR.3.3.1  
5 discusses the potential effects on the performance of the disposal system of drilling-induced  
6 flow, postdrilling processes (fluid extraction and injection), and flow through abandoned  
7 boreholes.

8  
9 *SCR.3.2.1.1 Historical, Current, and Near-Future Human-Initiated EPs*

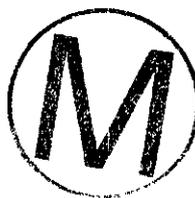

10  
11 Resource exploration and exploitation are the most common reasons for drilling in the  
12 Delaware Basin and are the most likely reasons for drilling in the near future. The WIPP  
13 location has been evaluated for the occurrence of natural resources in economic quantities.  
14 Powers et al. (1978) (Appendix GCR, Chapter 8) investigated the potential for exploitation of  
15 potash, hydrocarbons, caliche, gypsum, salt, uranium, sulfur, and lithium. Also, in 1995, the  
16 New Mexico Bureau of Mines and Mineral Resources (NMBMMR) performed a reevaluation  
17 of the mineral resources at and within 1 mile (1.6 kilometers) around the WIPP site.

18  
19 Potash resources in the vicinity of the WIPP are discussed in Section 2.3.1.1. Throughout the  
20 Carlsbad Potash District, commercial quantities of potash are restricted to the McNutt, which  
21 forms part of the Salado above the repository horizon. **Potash exploration** and evaluation  
22 boreholes have been drilled within and outside the controlled area.

23  
24 Drilling associated with **oil and gas exploration** and **oil and gas exploitation** currently takes  
25 place in the vicinity of the WIPP (see Section 2.3.1.2). For example, gas is extracted from  
26 reservoirs in the Morrow Formation, some 14,000 feet (4,200 meters) below the surface, and  
27 oil is extracted from shallower units within the Delaware Mountain Group, some 7,000 to  
28 8,000 feet (2,150 to 2,450 meters) below the surface. Three wells were drilled for oil and gas  
29 in the controlled area prior to the LWA of 1992. One of the three wells was drilled  
30 directionally from outside the controlled area.

31  
32 Secondary and tertiary oil and gas production techniques can involve the drilling of additional  
33 wells for the injection of fluid to enhance recovery. As indicated by the NMBMMR (1995),  
34 secondary production (waterflooding) is employed in the Delaware Basin, the nearest location  
35 to the WIPP site being approximately 2 miles (3 kilometers) from the outer boundary of the  
36 controlled area. Drilling associated with **enhanced oil and gas recovery** is expected to  
37 continue in the near future.

38  
39 Of the **other resources** investigated by Powers et al. (1978) (Appendix GCR, Chapter 8), the  
40 extraction of caliche, gypsum, salt, and lithium is not economically viable in the vicinity of  
41 the WIPP because of the widespread occurrence of more easily accessible deposits elsewhere  
42 in the region. Uranium is not present in economic quantities near the WIPP site, and no sulfur  
43 deposits were identified in the northern Delaware Basin.

1 Water is currently extracted from formations above the Salado, as discussed in Section  
2 2.3.1.3. The distribution of groundwater wells in the Delaware Basin is included in Appendix  
3 USDW (Section USDW.3). **Water resources exploration** and **groundwater exploitation**  
4 are expected to continue in the Delaware Basin.

5  
6 The only other drilling that has taken place or is expected to take place in the near future  
7 within or outside the controlled area is drilling associated with WIPP site investigations,  
8 which is discussed in Section SCR.2.3.8.2. **Geothermal** energy is not considered to be a  
9 potentially exploitable resource because economically attractive geothermal conditions do not  
10 exist in the northern Delaware Basin. Oil and gas production byproducts are disposed of  
11 underground in the WIPP region, but such **liquid waste disposal** does not involve drilling of  
12 additional boreholes. **Hydrocarbon storage** takes place in the Delaware Basin, but it  
13 involves gas injection through existing boreholes into depleted reservoirs (see, for example,  
14 Burton et al. 1993, 66 – 67). **Archeological investigations** in the WIPP area have involved  
15 only minor surface disturbances and have not involved drilling (see Section 2.3.2.3).

16  
17 In summary, drilling associated with water resources exploration, groundwater exploitation,  
18 potash exploration, oil and gas exploration, oil and gas exploitation, enhanced oil and gas  
19 recovery, and drilling to explore other resources has taken place and is expected to continue in  
20 the Delaware Basin. The potential effects of existing and possible near-future boreholes on  
21 fluid flow and radionuclide transport within the disposal system are discussed in Section  
22 SCR.3.3.1, where low consequence screening arguments are provided. No drilling associated  
23 with geothermal energy production, liquid waste disposal, hydrocarbon storage, and  
24 archeology has taken place in the Delaware Basin. Consistent with the future states  
25 assumptions in 40 CFR § 194.25(a), such drilling activities have been eliminated from  
26 performance assessment calculations on regulatory grounds. Also, consistent with 40 CFR  
27 § 194.33(b)(1), all near-future human-initiated EPs relating to **deliberate drilling intrusion**  
28 into the WIPP excavation have been eliminated from performance assessment calculations on  
29 regulatory grounds.

30  
31 *SCR.3.2.1.2 Future Human-Initiated EPs*

32  
33 Criteria in 40 CFR § 194.33 require that, to calculate the rates of future shallow and deep  
34 drilling in the Delaware Basin, the DOE should examine the historical rate of drilling for  
35 resources in the Delaware Basin.

36  
37 Shallow drilling associated with water, potash, sulfur, oil, and gas extraction has taken place  
38 in the Delaware Basin over the past 100 years. However, of these resources, only water and  
39 potash are present at shallow depths (less than 2,150 feet [655 meters] below the surface)  
40 within the controlled area. Thus, consistent with 40 CFR § 194.33(b)(4), the DOE has used  
41 the historical record of shallow drilling associated with **water resources exploration, potash**  
42 **exploration, and groundwater exploitation**, in calculations to determine the rate of future  
43 shallow drilling in the Delaware Basin (see Appendix DEL, Section DEL.7.4).

1 Oil and gas are the only known resources below the repository horizon that have been  
2 exploited over the past 100 years in the Delaware Basin. However, some potash and sulfur  
3 exploration boreholes have been drilled in the Delaware Basin to depths in excess of  
4 2,150 feet (655 meters) below the surface relative to where the drilling occurred. Thus,  
5 consistent with 40 CFR § 194.33(b)(3)(i), the DOE has used the historical record of deep  
6 drilling associated with **oil and gas exploration, oil and gas exploitation, enhanced oil and  
7 gas recovery, potash exploration,** and drilling associated with **other resources** (sulfur  
8 exploration), in the Delaware Basin in calculations to determine the rate of future deep drilling  
9 in the Delaware Basin (see Appendix DEL, Section DEL.7.4).

10  
11 Consistent with 40 CFR § 194.33 and the future states assumptions in 40 CFR § 194.25(a),  
12 drilling for purposes other than resource recovery (such as WIPP site investigation), and  
13 drilling activities that have not taken place in the Delaware Basin over the past 100 years,  
14 need not be considered in determining future drilling rates. Thus, drilling associated with  
15 **geothermal** energy production, **liquid waste disposal, hydrocarbon storage, and  
16 archeological investigations** has been eliminated from performance assessment calculations  
17 on regulatory grounds. Furthermore, consistent with 40 CFR §194.33(b)(1), all future human-  
18 initiated EPs relating to **deliberate drilling intrusion** into the WIPP excavation have been  
19 eliminated from performance assessment calculations on regulatory grounds.

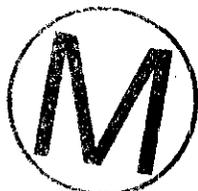

20  
21 **SCR.3.2.2 Excavation Activities**

22  
23 *Tunnelling and construction of underground facilities (for example, storage, disposal,  
24 accommodation) have been eliminated from performance assessment calculations on  
25 regulatory grounds. Historical, current, and near-future mining other than for potash and  
26 archeological excavations, have been eliminated from performance assessment calculations  
27 on the basis of low consequence to the performance of the disposal system. Future mining  
28 other than for potash, future archeological excavations, and deliberate mining intrusion into  
29 the disposal system have been eliminated from performance assessment calculations on  
30 regulatory grounds. The effects of historical, current, near-future, and future potash mining  
31 are accounted for in performance assessment calculations (Section SCR.3.3.2).*

32  
33 This section discusses historical, current and expected near-future excavation activities  
34 outside the controlled area, and excavation activities that may take place within or outside the  
35 controlled area in the future. Excavation may take place within the controlled area in the  
36 future after the end of the period of active institutional control (100 years after disposal).  
37 Section SCR.3.3.2 discusses the potential effects of excavations on the performance of the  
38 disposal system.

39  
40 **SCR.3.2.2.1 Historical, Current, and Near-Future Human-Initiated EPs**

41  
42 Excavation activities that can cause underground disturbances include mining, tunnelling,  
43 construction of underground storage or disposal facilities, and archeological investigations.

1 Potash is the only known economically viable resource in the vicinity of the WIPP that is  
2 recovered by underground mining (see Section 2.3.1). Potash is mined extensively in the  
3 region east of Carlsbad and up to 3.1 miles (5 kilometers) from the boundaries of the  
4 controlled area. According to existing plans and leases (see Chapter 2.0, Section 2.3.1.1),  
5 **potash mining** is expected to continue in the vicinity of the WIPP in the near future. The  
6 DOE assumes that all economically recoverable potash in the vicinity of the disposal system  
7 will be extracted in the near future. Excavation for **other resources** does take place elsewhere  
8 in the Delaware Basin. In numerous areas, sand, gravel, and caliche are produced, but in all  
9 cases, these are surface quarries that are generally shallow (tens of feet).

10  
11 **No construction of underground facilities (for example, storage, disposal,**  
12 **accommodation [that is, dwellings]) or tunnelling** has taken place in the Delaware Basin.  
13 Gas storage does take place in the Delaware Basin, but it involves injection through boreholes  
14 into depleted reservoirs, and not excavation (see, for example, Burton et al. 1993, 66 – 67).  
15 **Archeological excavations** in the WIPP area have involved only minor surface disturbances  
16 (see Section 2.3.2.3). The only other excavation activities that have taken place in the  
17 Delaware Basin are those associated with the construction of the WIPP repository; FEPs  
18 associated with the WIPP excavation are discussed in Section SCR.2.

19  
20 In summary, potash mining is currently taking place and is expected to continue in the vicinity  
21 of the WIPP in the near future. The potential effects of historical, current, and near-future  
22 potash mining are discussed in Section SCR.3.3.2, and are accounted for in performance  
23 assessment calculations. Excavation for resources other than potash and archeological  
24 excavations have taken place or are currently taking place in the Delaware Basin. These  
25 activities have not altered the geology of the controlled area significantly, and have been  
26 eliminated from performance assessment calculations on the basis of low consequence to the  
27 performance of the disposal system. Tunnelling and construction of underground facilities  
28 have not taken place in the Delaware Basin. Consistent with the future states assumptions in  
29 40 CFR § 194.25(a), such excavation activities have been eliminated from performance  
30 assessment calculations on regulatory grounds. Also, consistent with 40 CFR § 194.33(b)(1),  
31 all near-future human-initiated EPs relating to **deliberate mining intrusion** into the WIPP  
32 excavation have been eliminated from performance assessment calculations on regulatory  
33 grounds.

34  
35 *SCR.3.2.2.2 Future Human-Initiated EPs*

36  
37 According to 40 CFR § 194.32(b), consideration of future mining may be limited to mining  
38 within the disposal system at the locations of resources that are similar in quality and type to  
39 those currently extracted from the Delaware Basin. Potash is the only resource that has been  
40 identified within the controlled area in quality similar to that currently mined elsewhere in the  
41 Delaware Basin. Future mining for **other resources** has been eliminated from performance  
42 assessment calculations on regulatory grounds. Within the controlled area, the McNutt, which  
43 forms part of the Salado above the repository horizon, provides the only potash of appropriate  
44 quality. The extent of possible future **potash mining** within the controlled area (occurring

1 when active institutional controls are ineffective) is discussed in Section 2.3.1.1. The  
2 potential effects of future potash mining are discussed in Section SCR.3.3.2, and are  
3 accounted for in performance assessment calculations.  
4

5 Consistent with the future states assumptions in 40 CFR § 194.25(a), excavation activities that  
6 have not taken place in the Delaware Basin over the past 100 years need not be included in  
7 consideration of future human activities. Thus, **tunnelling, and construction of**  
8 **underground facilities (for example, storage, disposal, accommodation)** have been  
9 eliminated from performance assessment calculations on regulatory grounds. Also, consistent  
10 with 40 CFR § 194.32(a), which limits the scope of consideration of future human actions to  
11 mining and drilling, future **archeological excavations** have been eliminated from  
12 performance assessment calculations on regulatory grounds. Furthermore, consistent with  
13 40 CFR § 194.33(b)(1), all future human-initiated EPs relating to **deliberate mining**  
14 **intrusion** into the WIPP excavation have been eliminated from performance assessment  
15 calculations on regulatory grounds.  
16

### 17 SCR.3.2.3 Subsurface Explosions

18  
19 This section discusses subsurface explosions associated with **resource recovery and**  
20 **underground nuclear device testing** that may result in pathways for fluid flow between  
21 hydraulically conductive horizons. The potential effects of explosions on the hydrological  
22 characteristics of the disposal system are discussed in Section SCR.3.3.3.  
23

#### 24 SCR.3.2.3.1 Resource Recovery

25  
26 *Historical underground explosions for resource recovery have been eliminated from*  
27 *performance assessment calculations on the basis of low consequence to the performance of*  
28 *the disposal system. Future underground explosions for resource recovery have been*  
29 *eliminated from performance assessment calculations on regulatory grounds.*  
30

##### 31 SCR.3.2.3.1.1 *Historical, Current, and Near-Future Human-Initiated EPs*

32  
33 Neither small-scale nor regional-scale explosive techniques to enhance formation hydraulic  
34 conductivity form a part of current mainstream oil- and gas-production technology. Instead,  
35 controlled perforating and hydrofracturing are used to improve the performance of oil and gas  
36 boreholes in the Delaware Basin. However, small-scale explosions have been used in the past  
37 to fracture oil- and natural-gas-bearing units to enhance resource recovery. The size of  
38 explosion used to fracture an oil- or gas-bearing unit is limited by the need to contain the  
39 damage within the unit being exploited. In the area surrounding the WIPP, the stratigraphic  
40 units with oil and gas resources are too deep for explosions to affect the performance of the  
41 disposal system. Thus, the effects of **explosions for resource recovery** have been eliminated  
42 from performance assessment calculations on the basis of low consequence to the  
43 performance of the disposal system.  
44

1 *SCR.3.2.3.1.2 Future Human-Initiated EPs*

2  
3 Consistent with 40 CFR § 194.33(d), performance assessments need not analyze the effects of  
4 techniques used for resource recovery subsequent to the drilling of a future borehole.  
5 Therefore, future underground **explosions for resource recovery** have been eliminated from  
6 performance assessment calculations on regulatory grounds.

7  
8 *SCR.3.2.3.2 Underground Nuclear Device Testing*

9  
10 *Historical underground nuclear device testing has been eliminated from performance*  
11 *assessment calculations on the basis of low consequence to the performance of the disposal*  
12 *system. Future underground nuclear device testing has been eliminated from performance*  
13 *assessment calculations on regulatory grounds.*

14  
15 *SCR.3.2.3.2.1 Historical, Current, and Near-Future Human-Initiated EPs*

16  
17 The Delaware Basin has been used for an isolated nuclear test. This test, Project Gnome  
18 (Rawson et al. 1965, 5, 8, 35), took place in 1961 at a location approximately 8 miles (13  
19 kilometers) southwest of the WIPP waste disposal region. Project Gnome was  
20 decommissioned in 1979.

21  
22 The primary objective of Project Gnome was to study the effects of an underground nuclear  
23 explosion in salt. The Gnome experiment involved the detonation of a 3.1 kiloton nuclear  
24 device at a depth of 1,190 feet (360 meters) in the bedded salt of the Salado. The explosion  
25 created an approximately spherical cavity of about 950,000 cubic feet (27,000 cubic meters)  
26 and caused surface displacements in a radius of 1,180 feet (360 meters). No earth tremors  
27 perceptible to humans were reported at distances over 25 miles (40 kilometers) from the  
28 explosion. A zone of increased permeability was observed to extend at least 150 feet  
29 (46 meters) laterally from, and 344 feet (105 meters) above, the point of the explosion. The  
30 test had no significant effects on the geological characteristics of the WIPP disposal system.  
31 Thus, historical **underground nuclear device testing** has been eliminated from performance  
32 assessment calculations on the basis of low consequence to the performance of the disposal  
33 system. There are no existing plans for underground nuclear device testing in the vicinity of  
34 the WIPP in the near future.

35  
36 *SCR.3.2.3.2.2 Future Human-Initiated EPs*

37  
38 The criterion in 40 CFR § 194.32(a), relating to the scope of performance assessments, limits  
39 the consideration of future human actions to mining and drilling. Therefore, future  
40 **underground nuclear device testing** has been eliminated from performance assessment  
41 calculations on regulatory grounds.  
42

1 **SCR.3.3 Subsurface Hydrological and Geochemical EPs**

2  
3 The human-initiated EPs considered in this section relate to the potential subsurface  
4 hydrological and geochemical effects of the activities involving drilling, excavation, and  
5 subsurface explosions, discussed in Section SCR.3.2. The discussion here is limited to those  
6 human activities not eliminated from performance assessment calculations on regulatory  
7 grounds in Section SCR.3.2.

8  
9 **SCR.3.3.1 Borehole Fluid Flow**

10  
11 Borehole fluid flow during drilling, fluid extraction and injection through boreholes, and flow  
12 through abandoned boreholes could result in hydrological or geochemical disturbances of the  
13 disposal system and could affect radionuclide transport.

14  
15 **SCR.3.3.1.1 Drilling-Induced Flow**

16  
17 *Drilling fluid flow, drilling fluid loss, and blowouts associated with historical, current, near-*  
18 *future, and future boreholes that do not intersect the waste disposal region, have been*  
19 *eliminated from performance assessment calculations on the basis of low consequence to the*  
20 *performance of the disposal system. The possibility of a future deep borehole penetrating a*  
21 *waste panel, such that drilling-induced flow results in transport of radionuclides to the land*  
22 *surface or to overlying hydraulically conductive units, is accounted for in performance*  
23 *assessment calculations. Drilling fluid loss into waste panels is accounted for in performance*  
24 *assessment calculations. The possibility of a deep borehole penetrating both the waste*  
25 *disposal region and a Castile brine reservoir is accounted for in performance assessment*  
26 *calculations. Geochemical changes that occur within the controlled area as a result of*  
27 *historical, current, near-future, and future drilling-induced flow are accounted for in*  
28 *performance assessment calculations.*

29  
30 Borehole circulation fluid could be lost to thief zones encountered during drilling, or fluid  
31 could flow from pressurized zones through the borehole to the land surface (blowout) or to a  
32 thief zone. Such drilling-related EPs could influence groundwater flow and, potentially,  
33 radionuclide transport in the affected units. Future drilling within the controlled area could  
34 result in direct releases of radionuclides to the land surface or transport of radionuclides  
35 between hydraulically conductive units.

36  
37 Movement of brine from a pressurized zone, through a borehole, into potential thief zones  
38 such as the Salado interbeds or the Culebra, could result in geochemical changes and altered  
39 radionuclide migration rates in these units.

40  
41 **SCR.3.3.1.1.1 Historical, Current, and Near-Future Human-Initiated EPs**

42  
43 As discussed in Section SCR.3.2.1, drilling associated with water resources exploration,  
44 groundwater exploitation, potash exploration, oil and gas exploration, oil and gas exploitation,

1 enhanced oil and gas recovery, and drilling to explore other resources has taken place or is  
2 currently taking place outside the controlled area in the Delaware Basin. These drilling  
3 activities are expected to continue in the vicinity of the WIPP in the near future.

4  
5 *Hydraulic effects of drilling-induced flow*

6  
7 **Drilling fluid flow** will not affect hydraulic conditions in the disposal system significantly  
8 unless there is substantial **drilling fluid loss** to a thief zone, such as the Culebra. Typically,  
9 zones into which significant borehole circulation fluid is lost are isolated through injection of  
10 materials to reduce permeability or through casing and cementing programs. Assuming such  
11 operations are successful, drilling fluid loss in the near future outside the controlled area will  
12 not affect the hydrology of the disposal system significantly.

13  
14 Naturally occurring brine and gas pockets have been encountered during drilling in the  
15 Delaware Basin. Brine pockets have been intersected in the Castile (as discussed in Section  
16 2.2.1.3) and in the Salado above the WIPP horizon (Section 2.2.1.2.2). Gas **blowouts** have  
17 occurred during drilling in the Salado. Usually, such events result in brief interruptions in  
18 drilling while the intersected fluid pocket is allowed to depressurize through flow to the  
19 surface (for a period lasting from a few hours to a few days). Drilling then restarts with an  
20 increased drilling mud weight. Under these conditions, blowouts in the near future will cause  
21 isolated hydraulic disturbances, but will not affect the hydrology of the disposal system  
22 significantly.

23  
24 Potentially, the most significant disturbance to the disposal system could occur if an  
25 uncontrolled blowout during drilling resulted in substantial flow through the borehole from a  
26 pressurized zone to a thief zone. For example, if a borehole penetrates a brine reservoir in the  
27 Castile, brine could flow through the borehole to the Culebra, and, as a result, could affect  
28 hydraulic conditions in the Culebra. The potential effects of such an event can be compared  
29 to the effects of long-term fluid flow from deep overpressurized units to the Culebra through  
30 abandoned boreholes. Wallace (1996a) analysed the potential effects of flow through  
31 abandoned boreholes in the future within the controlled area (as discussed in Section  
32 SCR.3.3.1.4.2), and concluded that interconnections between the Culebra and deep units  
33 could be eliminated from performance assessment calculations on the basis of low  
34 consequence. Long-term flow through abandoned boreholes would have a greater  
35 hydrological impact in the Culebra than short-term drilling-induced flow outside the  
36 controlled area. Thus, the effects of fluid flow during drilling in the near future have been  
37 eliminated from performance assessment calculations on the basis of low consequence to the  
38 performance of the disposal system.

39  
40 In summary, drilling fluid flow, drilling fluid loss, and blowouts associated with historical,  
41 current, and near-future boreholes have been eliminated from performance assessment  
42 calculations on the basis of low consequence to the performance of the disposal system.

1 *Geochemical effects of drilling-induced flow*

2  
3 Radionuclide migration rates are governed by the coupled effects of hydrological and  
4 geochemical processes, as discussed in Sections SCR.2.6 and SCR.2.7. Human-initiated EPs  
5 outside the controlled area could affect the geochemistry of units within the controlled area if  
6 they occur sufficiently close to the edge of the controlled area. Movement of brine from a  
7 pressurized reservoir in the Castile through a borehole into potential thief zones, such as the  
8 Salado interbeds or the Culebra, could cause **drilling-induced geochemical changes** resulting  
9 in altered radionuclide migration rates in these units through their effects on colloid transport  
10 and sorption (colloid transport may enhance radionuclide migration, while radionuclide  
11 migration may be retarded by sorption).

12  
13 The treatment of colloids in performance assessment calculations is described in Sections  
14 6.4.3.6 and 6.4.6.2.2. The repository and its contents provide the main source of colloids in  
15 the disposal system. By comparison, Castile brines have relatively low total colloid  
16 concentrations. Therefore, changes in colloid transport in units within the controlled area as a  
17 result of historical, current, and near-future drilling-induced flow have been eliminated from  
18 performance assessment calculations on the basis of low consequence to the performance of  
19 the disposal system.

20  
21 Sorption within the Culebra is accounted for in performance assessment calculations as  
22 discussed in Section 6.4.6.2. The sorption model comprises an equilibrium, sorption isotherm  
23 approximation, employing distribution coefficients ( $K_d$ s) applicable to dolomite in the Culebra  
24 (Appendix MASS, Section MASS.15.2). The CDFs of distribution coefficients used  
25 (Appendix PAR) are derived from a suite of experimental studies that include measurements  
26 of  $K_d$ s for actinides in a range of chemical systems including Culebra and Castile brines,  
27 Culebra brines, and Salado brines. Therefore, any changes in sorption geochemistry in the  
28 Culebra within the controlled area as a result of historical, current, and near-future drilling-  
29 induced flow are accounted for in performance assessment calculations.

30  
31 Sorption within the Dewey Lake is accounted for in performance assessment calculations, as  
32 discussed in Section 6.4.6.6. It is assumed that the sorptive capacity of the Dewey Lake is  
33 sufficiently large to prevent any radionuclides that enter the Dewey Lake from being released  
34 over 10,000 years (Wallace et al. 1995). Sorption within other geological units of the disposal  
35 system has been eliminated from performance assessment calculations on the basis of  
36 beneficial consequence to the performance of the disposal system. The effects of changes in  
37 sorption in the Dewey Lake and other units within the controlled area as a result of historical,  
38 current, and near-future drilling-induced flow have been eliminated from performance  
39 assessment calculations on the basis of low consequence to the performance of the disposal  
40 system.

1 *SCR.3.3.1.1.2 Future Human-Initiated EPs – Boreholes that Intersect the Waste Disposal*  
2 *Region*

3  
4 The consequences of drilling within the controlled area in the future will primarily depend on  
5 the location of the borehole. Potentially, future deep drilling could penetrate the waste  
6 disposal region. If the borehole intersects the waste in the disposal rooms, radionuclides  
7 could be transported as a result of **drilling fluid flow**: releases to the accessible environment  
8 may occur as material entrained in the circulating drilling fluid is brought to the surface (see  
9 Section SCR.2.6.3). Also, during drilling, contaminated brine may flow up the borehole and  
10 reach the surface, depending on fluid pressure within the waste disposal panels; **blowout**  
11 conditions could prevail if the waste panel were sufficiently pressurized at the time of  
12 intrusion. Alternatively, hydraulic and geochemical conditions in the waste panel could be  
13 affected as a result of **drilling fluid loss** to the panel and **drilling-induced geochemical**  
14 **changes**.

15  
16 *Hydraulic effects of drilling-induced flow*

17  
18 The possibility of a future borehole penetrating a waste panel, so that drilling fluid flow and,  
19 potentially, blowout, results in transport of radionuclides to the land surface or to overlying  
20 hydraulically conductive units, is accounted for in performance assessment calculations.

21  
22 The units intersected by the borehole may provide sources for fluid flow (brine, oil, or gas) to  
23 the waste panel during drilling. In the vicinity of the WIPP, the Castile that underlies the  
24 Salado contains isolated volumes of brine at fluid pressures greater than hydrostatic. A future  
25 borehole that penetrates a Castile brine reservoir could provide a connection for brine flow  
26 from the reservoir to the waste panel, thus increasing fluid pressure and brine volume in the  
27 waste panel. The possibility of a deep borehole penetrating both a waste panel and a brine  
28 reservoir is accounted for in performance assessment calculations.

29  
30 A future borehole that is drilled through a disposal room wall, but does not intersect waste,  
31 could penetrate a brine reservoir underlying the waste disposal region. Such an event would  
32 depressurize the brine reservoir to some extent, and thus would affect the consequences of any  
33 subsequent intersections of the reservoir. The possibility for a borehole to depressurize a  
34 brine reservoir underlying the waste disposal region is accounted for in performance  
35 assessment calculations.

36  
37 Penetration of an underpressurized unit underlying the Salado could result in flow and  
38 radionuclide transport from the waste panel to the underlying unit during drilling, although  
39 drillers would minimize such fluid loss to a thief zone through the injection of materials to  
40 reduce permeability or through the use of casing and cementing. Also, the permeabilities of  
41 formations underlying the Salado are less than the permeability of the Culebra (Wallace  
42 1996a). Thus, the consequences associated with radionuclide transport to an underpressurized  
43 unit below the waste panels during drilling will be less significant, in terms of disposal system  
44 performance, than the consequences associated with radionuclide transport to the land surface

1 or to the Culebra during drilling. Through this comparison, drilling events that result in  
2 penetration of underpressurized units below the waste-disposal region have been eliminated  
3 from performance assessment calculations on the basis of beneficial consequence to the  
4 performance of the disposal system.

5  
6 In evaluating the potential consequences of drilling fluid loss to a waste panel, two types of  
7 drilling events need to be considered - those that intercept pressurized fluid in underlying  
8 formations such as the Castile (defined in Section 6.3.2.2 as E1 events) and those that do not  
9 (E2 events). A possible hydrological effect would be to make a greater volume of brine  
10 available for gas generation processes and thereby increase gas volumes at particular times in  
11 the future. As discussed in Section 6.4.12.6, of boreholes that intersect a waste panel in the  
12 future, 8 percent are assumed to be E1 events and 92 percent are E2 events. For either type of  
13 drilling event, on the basis of current drilling practices, the driller is assumed to pass through  
14 the repository rapidly. Relatively small amounts of drilling fluid loss may not be noticed or  
15 may not give rise to concern. Larger fluid losses would lead to the driller injecting materials  
16 to reduce permeability, or to the borehole being cased and cemented, to limit the loss of  
17 drilling fluid.

18  
19 For boreholes that intersect pressurized brine reservoirs, the volume of fluid available to flow  
20 up a borehole will be significantly greater than the volume of any drilling fluid that could be  
21 lost. This greater volume of brine is accounted for in performance assessment calculations,  
22 and is allowed to enter the disposal room (see Section 6.4.7). Thus, the effects of drilling  
23 fluid loss will be small by comparison to the potential flow of brine from pressurized brine  
24 reservoirs. Therefore, the effects of drilling fluid loss for E1 drilling events have been  
25 eliminated from performance assessment calculations on the basis of low consequence to the  
26 performance of the disposal system.

27  
28 For boreholes that do not intersect pressurized brine reservoirs the treatment of the disposal  
29 room implicitly accounts for the potential for greater gas generation resulting from drilling  
30 fluid loss. Thus, the hydrological effects of drilling fluid loss for E2 drilling events are  
31 accounted for in performance assessment calculations within the conceptual model of the  
32 disposal room for drilling intrusions.

33  
34 *Geochemical effects of drilling-induced flow*

35  
36 Drilling fluid loss to a waste panel could modify the chemistry of disposal room brines in a  
37 manner that would affect the solubility of radionuclides and the source term available for  
38 subsequent transport from the disposal room. The majority of drilling fluids used are likely to  
39 be locally derived, and their bulk chemistry will be similar to fluids currently present in the  
40 disposal system. In addition, the presence of the MgO chemical conditioner in the disposal  
41 rooms will buffer the chemistry across a range of fluid compositions, as discussed in detail in  
42 Appendix SOTERM. Furthermore, for E1 drilling events, the volume of Castile brine that  
43 flows into the disposal room will be greater than that of any drilling fluids; Castile brine  
44 chemistry is accounted for in performance assessment calculations. Thus, the effects on

1 radionuclide solubility of drilling fluid loss to the disposal room have been eliminated from  
2 performance assessment calculations on the basis of low consequence to the performance of  
3 the disposal system.

4  
5 Movement of brine from a pressurized reservoir in the Castile through a borehole into thief  
6 zones, such as the Salado interbeds or the Culebra, could result in geochemical changes in the  
7 receiving units, and thus alter radionuclide migration rates in these units through their effects  
8 on colloid transport and sorption.

9  
10 The repository and its contents provide the main source of colloids in the disposal system.  
11 Thus, colloid transport in the Culebra within the controlled area as a result of drilling-induced  
12 flow associated with boreholes that intersect the waste disposal region are accounted for in  
13 performance assessment calculations, as described in Sections 6.4.3.6 and 6.4.6.2.1. The  
14 Culebra is the most transmissive unit in the disposal system and it is the most likely unit  
15 through which significant radionuclide transport could occur. Therefore, colloid transport in  
16 units other than the Culebra, as a result of drilling-induced flow associated with boreholes that  
17 intersect the waste disposal region, has been eliminated from performance assessment  
18 calculations on the basis of low consequence to the performance of the disposal system.

19  
20 As discussed in Section SCR.3.3.1.1.1, sorption within the Culebra is accounted for in  
21 performance assessment calculations. The sorption model used incorporates the effects of  
22 changes in sorption in the Culebra as a result of drilling-induced flow associated with  
23 boreholes that intersect the waste disposal region.

24  
25 Consistent with the screening discussion in Section SCR.3.3.1.1.1, the effects of changes in  
26 sorption in the Dewey Lake inside the controlled area as a result of drilling-induced flow  
27 associated with boreholes that intersect the waste disposal region have been eliminated from  
28 performance assessment calculations on the basis of low consequence to the performance of  
29 the disposal system. Sorption within other geological units of the disposal system has been  
30 eliminated from performance assessment calculations on the basis of beneficial consequence  
31 to the performance of the disposal system.

32  
33 *SCR.3.3.1.1.3 Future Human-Initiated EPs – Boreholes that do not Intersect the Waste*  
34 *Disposal Region*

35  
36 Future boreholes that do not intersect the waste disposal region could nevertheless encounter  
37 contaminated material by intersecting a region into which radionuclides have migrated from  
38 the disposal panels, or could affect hydrogeological conditions within the disposal system.  
39 Consistent with the containment requirements in 40 CFR § 191.13(a), performance  
40 assessments need not evaluate the effects of the intersection of contaminated material outside  
41 the controlled area.

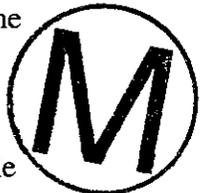

1 Movement of brine from a pressurized reservoir in the Castile, through a borehole, into thief  
2 zones such as the Salado interbeds or the Culebra, could result in **drilling-induced**  
3 **geochemical changes** and altered radionuclide migration rates in these units.

4  
5 *Hydraulic effects of drilling-induced flow*

6  
7 If radionuclides migrate away from the waste disposal panels through the interbeds, then deep  
8 drilling could result in the intersection of a contaminated region within the interbeds.  
9 Consequently, contaminated drill cuttings or brine could be transported to the land surface  
10 through **drilling fluid flow**. Performance assessment calculations show that lateral  
11 radionuclide migration through the Salado from the waste disposal region occurs most  
12 extensively in the undisturbed performance scenario; in this case radionuclides are transported  
13 through MB139. Based on the calculations of undisturbed performance, Economy (1996)  
14 determined the maximum quantity of radioactive material that could be transported from the  
15 waste disposal region into MB139 during the 10,000 year regulatory period. Economy (1996)  
16 calculated the normalized amount of radioactive material that enters MB139 to be  
17 approximately 0.13 EPA units; this quantity was derived using an equation similar to that used  
18 for determining normalized radionuclide releases to the accessible environment, which is  
19 presented as Equation (1) in Chapter 6.0.

20  
21 The amount of contaminated material in MB139 that could be removed by drilling during the  
22 regulatory period depends primarily on the number of deep boreholes expected to be drilled in  
23 the unit area of the controlled area in 10,000 years and the cross-sectional area of these  
24 boreholes. As discussed in Appendix DEL (Section DEL.7.4), the expected rate of drilling is  
25 approximately 47 boreholes per square kilometer per 10,000 years. Based on a borehole  
26 diameter of 1.02 feet (0.311 meters), the cross-sectional area of each borehole within the  
27 Salado is approximately 0.76 square meters. Thus, in 10,000 years approximately  $3.6 \times 10^{-6}$   
28 of the interbed volume will be removed from the Salado. Conservatively assuming that  
29 MB139 within the disposal system is uniformly contaminated for the entire 10,000 years with  
30 0.13 normalized release units, then approximately  $3.6 \times 10^{-6}$  of the 0.13 normalized release  
31 units can be removed by drilling directly to the surface. This is approximately  $5 \times 10^{-7}$   
32 normalized release units. This quantity is insignificant. Therefore, releases resulting from the  
33 intersection of contaminated material in MB139 are screened out on the basis of low  
34 consequence.

35  
36 Boreholes penetrating a contaminated Culebra can also release radionuclides to the accessible  
37 environment. The maximum normalized release of radioactive material to the Culebra in  
38 1996 performance assessment calculations is approximately 18 EPA release units. As  
39 discussed in Appendix DEL (Section DEL.7.4), approximately 69 deep and shallow boreholes  
40 per 10,000 years are assumed in performance assessment calculations. By the method  
41 presented in the previous paragraph, the maximum normalized release from the Culebra by  
42 direct drilling through a plume is on the order of  $9 \times 10^{-5}$ . This is insignificant. Therefore,  
43 radionuclide releases resulting from intersection of contaminated material in the Culebra have  
44 been eliminated from performance assessment calculations on the basis of low consequence.

1 Future boreholes could affect the hydraulic conditions in the disposal system. As discussed in  
2 Section SCR.3.3.1.1.1, intersection of pockets of pressurized gas and brine, and **drilling fluid**  
3 **loss**, are likely to result in short-term, isolated hydraulic disturbances, and will not affect the  
4 hydrology of the disposal system significantly. Potentially, the most significant hydraulic  
5 disturbance to the disposal system could occur if an uncontrolled **blowout** during drilling  
6 resulted in substantial flow through the borehole from a pressurized zone to a thief zone. For  
7 example, if a borehole penetrates a brine reservoir in the Castile, brine could flow through the  
8 borehole to the Culebra, and, as a result, could affect hydraulic conditions in the Culebra. The  
9 potential effects of such an event can be compared to the effects of long-term fluid flow from  
10 deep overpressurized units to the Culebra through abandoned boreholes. Wallace (1996a)  
11 analyzed the potential effects of such interconnections in the future within the controlled area  
12 (as discussed in Section SCR.3.3.1.4.2), and concluded that flow through abandoned  
13 boreholes between the Culebra and deep units could be eliminated from performance  
14 assessment calculations on the basis of low consequence. Long-term flow through abandoned  
15 boreholes would have a greater impact on Culebra hydrology than short-term drilling-induced  
16 flow within the controlled area. Thus, the effects of fluid flow during drilling in the future  
17 have been eliminated from performance assessment calculations on the basis of low  
18 consequence to the performance of the disposal system.

19  
20 In summary, drilling fluid flow, drilling fluid loss, and blowouts associated with future  
21 boreholes that do not intersect the waste disposal region have been eliminated from  
22 performance assessment calculations on the basis of low consequence to the performance of  
23 the disposal system.

24  
25 *Geochemical effects of drilling-induced flow*

26  
27 Movement of brine from a pressurized reservoir in the Castile through a borehole into thief  
28 zones, such as the Salado interbeds or the Culebra, could cause geochemical changes resulting  
29 in altered radionuclide migration rates in these units through their effects on colloid transport  
30 and sorption.

31  
32 The contents of the waste disposal panels provide the main source of colloids in the disposal  
33 system. Thus, consistent with the discussion in Section SCR.3.3.1.1.1, colloid transport as a  
34 result of drilling-induced flow associated with future boreholes that do not intersect the waste  
35 disposal region has been eliminated from performance assessment calculations on the basis of  
36 low consequence to the performance of the disposal system.

37  
38 As discussed in Section SCR.3.3.1.1.1, sorption within the Culebra is accounted for in  
39 performance assessment calculations. The sorption model accounts for the effects of changes  
40 in sorption in the Culebra as a result of drilling-induced flow associated with boreholes that  
41 do not intersect the waste disposal region.

42  
43 Consistent with the screening discussion in Section SCR.3.3.1.1.1, the effects of changes in  
44 sorption in the Dewey Lake within the controlled area as a result of drilling-induced flow

1 associated with boreholes that do not intersect the waste disposal region have been eliminated  
2 from performance assessment calculations on the basis of low consequence to the  
3 performance of the disposal system. Sorption within other geological units of the disposal  
4 system has been eliminated from performance assessment calculations on the basis of  
5 beneficial consequence to the performance of the disposal system.

6  
7 *SCR.3.3.1.2 Fluid Extraction*

8  
9 *Historical, current, and near-future groundwater, oil, and gas extraction outside the*  
10 *controlled area has been eliminated from performance assessment calculations on the basis*  
11 *of low consequence to the performance of the disposal system. Groundwater, oil, and gas*  
12 *extraction through future boreholes has been eliminated from performance assessment*  
13 *calculations on regulatory grounds.*

14  
15 The extraction of fluid could alter fluid-flow patterns in the target horizons, or in overlying  
16 units as a result of a failed borehole casing. Also, the removal of confined fluid from oil- or  
17 gas-bearing units can cause compaction in some geologic settings, potentially resulting in  
18 subvertical fracturing and surface subsidence.

19  
20 *SCR.3.3.1.2.1 Historical, Current, and Near-Future Human-Initiated EPs*

21  
22 As discussed in Section SCR.3.2.1, water, oil, and gas production are the only activities  
23 involving fluid extraction through boreholes that have taken place or are currently taking place  
24 in the vicinity of the WIPP. These activities are expected to continue in the vicinity of the  
25 WIPP in the near future.

26  
27 **Groundwater extraction** outside the controlled area from formations above the Salado could  
28 affect groundwater flow. The Dewey Lake contains a productive zone of saturation south of  
29 the WIPP site. Several wells operated by the J.C. Mills Ranch south of the WIPP produce  
30 water from the Dewey Lake to supply livestock (see Section 2.2.1.4.2.1). Also, water has  
31 been extracted from the Culebra at the Engle Well approximately 6 miles south of the  
32 controlled area to provide water for livestock. No water wells in other areas in the vicinity of  
33 the WIPP are expected to be drilled in the near future because of the high concentrations of  
34 total dissolved solids in the groundwater.

35  
36 If contaminated water intersects a well while it is producing, then contaminants could be  
37 pumped to the surface. Consistent with the containment requirements in 40 CFR § 191.13(a),  
38 performance assessments need not evaluate radiation doses that might result from such an  
39 event. However, compliance assessments must include any such events in dose calculations  
40 for evaluating compliance with the individual protection requirements in 40 CFR § 191.15.  
41 As discussed in Chapter 8.0, under undisturbed conditions, there are no calculated  
42 radionuclide releases to units containing producing wells.

1 Pumping from wells at the J.C. Mills Ranch may have resulted in reductions in hydraulic head  
2 in the Dewey Lake within southern regions of the controlled area, leading to increased  
3 hydraulic head gradients. However, these changes in the groundwater flow conditions in the  
4 Dewey Lake will have no significant effects on the performance of the disposal system,  
5 primarily because of the sorptive capacity of the Dewey Lake (see Section 6.4.6.6).  
6 Retardation of any radionuclides that enter the Dewey Lake will be such that no radionuclides  
7 will migrate through the Dewey Lake to the accessible environment within the 10,000-year  
8 regulatory period.

9  
10 The effects of groundwater extraction from the Culebra from a well 6 miles south of the  
11 controlled area have been evaluated by Wallace (1996b), using an analytical solution for  
12 Darcian fluid flow in a continuous porous medium. Wallace (1996b) showed that such a well  
13 pumping at about 0.5 gallons per minute for 10,000 years will induce a hydraulic head  
14 gradient across the controlled area of about  $4 \times 10^{-5}$ . The hydraulic head gradient across the  
15 controlled area currently ranges from between 0.001 to 0.007. Therefore, pumping from the  
16 Engle Well will have only minor effects on the hydraulic head gradient within the controlled  
17 area even if pumping were to continue for 10,000 years. Thus, the effects of historical,  
18 current, and near-future groundwater extraction outside the controlled area have been  
19 eliminated from performance assessment calculations on the basis of low consequence to the  
20 performance of the disposal system.

21  
22 **Oil and gas extraction** outside the controlled area could affect the hydrology of the disposal  
23 system. However, the horizons that act as oil and gas reservoirs are sufficiently below the  
24 repository for changes in fluid-flow patterns to be of low consequence, unless there is fluid  
25 leakage through a failed borehole casing. Also, oil and gas production horizons in the  
26 Delaware Basin are well-lithified rigid strata, so oil and gas extraction is not likely to result in  
27 compaction and subsidence (Brausch et al. 1982, 52, 61). Furthermore, the plasticity of the  
28 salt formations in the Delaware Basin will limit the extent of any fracturing caused by  
29 compaction of underlying units. Thus, neither the extraction of gas from reservoirs in the  
30 Morrow Formation (some 14,000 feet [4,200 meters] below the surface), nor extraction of oil  
31 from the shallower units within the Delaware Mountain Group (about 4,000 to 8,000 feet  
32 [1,250 to 2,450 meters] below the surface) will lead to compaction and subsidence. In  
33 summary, historical, current, and near-future oil and gas extraction outside the controlled area  
34 has been eliminated from performance assessment calculations on the basis of low  
35 consequence to the performance of the disposal system.

36  
37 *SCR.3.3.1.2.2 Future Human-Initiated EPs*

38  
39 Consistent with 40 CFR § 194.33(d), performance assessments need not analyze the effects of  
40 techniques used for resource recovery subsequent to the drilling of a future borehole.  
41 Therefore, **groundwater extraction** and **oil and gas extraction** through future boreholes  
42 have been eliminated from performance assessment calculations on regulatory grounds.

1 SCR.3.3.1.3 Fluid Injection

2  
3 *The hydrological effects of historical, current, and near-future fluid injection (liquid waste*  
4 *disposal, enhanced oil and gas production, and hydrocarbon storage) through boreholes*  
5 *outside the controlled area have been eliminated from performance assessment calculations*  
6 *on the basis of low consequence to the performance of the disposal system. Geochemical*  
7 *changes that occur inside the controlled area as a result of fluid flow associated with*  
8 *historical, current and near-future fluid injection are accounted for in performance*  
9 *assessment calculations. Liquid waste disposal, enhanced oil and gas production, and*  
10 *hydrocarbon storage involving future boreholes has been eliminated from performance*  
11 *assessment calculations on regulatory grounds.*

12  
13 The injection of fluids could alter fluid-flow patterns in the target horizons or, if there is  
14 accidental leakage through a borehole casing, in any other intersected hydraulically conductive  
15 zone. Injection of fluids through a leaking borehole could also result in geochemical changes  
16 and altered radionuclide migration rates in the thief units.

17  
18 SCR.3.3.1.3.1 Historical, Current, and Near-Future Human-Initiated EPs

19  
20 The only historical and current activities involving fluid injection through boreholes in the  
21 Delaware Basin are **enhanced oil and gas production** (waterflooding), **hydrocarbon**  
22 **storage** (gas reinjection), and **liquid waste disposal** (by-products from oil and gas  
23 production). These fluid injection activities are expected to continue in the vicinity of the  
24 WIPP in the near future.

25  
26 Hydraulic fracturing of oil- or gas-bearing units is currently used to improve the performance  
27 of hydrocarbon reservoirs in the Delaware Basin. Fracturing is induced during a short period  
28 of high-pressure fluid injection, resulting in increased hydraulic conductivity near the  
29 borehole. Normally, this controlled fracturing is confined to the pay zone and is unlikely to  
30 affect overlying strata.

31  
32 Secondary production techniques, such as waterflooding, that are used to maintain reservoir  
33 pressure and displace oil are currently employed in hydrocarbon reservoirs in the Delaware  
34 Basin (Brausch et al. 1982, 29 – 30). Reinjection of gas for storage currently takes place in a  
35 depleted gas field in the Morrow Formation of the Delaware Basin (Burton et al. 1993,  
36 66 – 67). Similarly, disposal of liquid by-products from oil and gas production involves  
37 injection of fluid into depleted reservoirs. Such fluid injection techniques result in  
38 repressurization of the depleted target reservoir and mitigates any effects of fluid withdrawal.

39  
40 The most significant effects of fluid injection would arise from substantial and uncontrolled  
41 fluid leakage through a failed borehole casing. The highly saline environment of some units  
42 can promote rapid corrosion of well casings and may result in fluid loss from boreholes.

1 *Hydraulic effects of leakage through injection boreholes*

2  
3 The Vacuum field (located in the Capitan Reef, some 20 miles [30 kilometers] northeast of  
4 the WIPP site) and the Rhodes-Yates field (located in the back reef of the Capitan, some  
5 45 miles [70 kilometers] southeast of the WIPP site) have been waterflooded for 40 years with  
6 confirmed leaking wells, which have resulted in brine entering the Salado and other  
7 formations above the Salado (see, for example, Silva 1994, 67-68). Currently, saltwater  
8 disposal takes place in the vicinity of the WIPP into formations below the Castile. However,  
9 leakages from saltwater disposal wells or waterflood wells in the near future in the vicinity of  
10 the WIPP are unlikely to occur because of the following:

- 11
- 12 • There are significant differences between the geology and lithology in the vicinity of  
13 the disposal system and that of the Vacuum and Rhodes-Yates Fields. The WIPP is  
14 located in the Delaware Basin in a fore reef environment, where a thick zone of  
15 anhydrite and halite (the Castile) exists. In the vicinity of the WIPP, oil is produced  
16 from the Brushy Canyon Formation at depths greater than 7,000 feet (2100 meters).  
17 By contrast, the Castile is not present at either the Vacuum or the Rhodes-Yates Field,  
18 which lie outside the Delaware Basin.<sup>5</sup> Oil production at the Vacuum Field is from the  
19 San Andres and Grayburg Formations at depths of approximately 4,500 feet (1400  
20 meters), and oil production at the Rhodes-Yates Field is from the Yates and Seven  
21 Rivers Formations at depths of approximately 3,000 feet (900 meters). Waterflooding  
22 at the Rhodes-Yates Field involves injection into a zone only 200 feet (60 meters)  
23 below the Salado. There are more potential thief zones below the Salado near the  
24 WIPP than at the Rhodes-Yates or Vacuum Fields; the Salado in the vicinity of the  
25 WIPP is therefore less likely to receive any fluid that leaks from an injection borehole.  
26 Additionally, the oil pools in the vicinity of the WIPP are characterized by channel  
27 sands with thin net pay zones, low permeabilities, high irreducible water saturations,  
28 and high residual oil saturations. Therefore, waterflooding of oil fields in the vicinity  
29 of the WIPP on the scale of that undertaken in the Vacuum or the Rhodes-Yates Field  
30 is unlikely.
  - 31
  - 32 • New Mexico state regulations require the emplacement of a salt isolation casing string  
33 for all wells drilled in the potash enclave, which includes the WIPP area, to reduce the  
34 possibility of petroleum wells leaking into the Salado. Also, injection pressures are  
35 not allowed to exceed the pressure at which the rocks fracture. The injection pressure  
36 gradient must be kept below 0.2 pounds per square inch per foot ( $4.5 \times 10^3$  pascals per  
37 meter) above hydrostatic if fracture pressures are unknown. Such controls on fluid  
38 injection pressures limit the potential magnitude of any leakages from injection  
39 boreholes.
  - 40

---

<sup>5</sup> The Delaware Basin is defined in the preamble to 40 CFR Part 194 to be "those surface and subsurface formations which lie inside the innermost edge of the Capitan Reef."

- Recent improvements in well completion practices and reservoir operations management have reduced the occurrences of leakages from injection wells. For example, injection pressures during waterflooding are typically kept below about one pounds per square inch per foot ( $23 \times 10^3$  pascals per meter) to avoid fracture initiation. Also, wells are currently completed using cemented and perforated casing, rather than the open-hole completions used in the early Rhodes-Yates wells.

Any injection well leakages that do occur in the vicinity of the WIPP in the near future are more likely to be associated with liquid waste disposal than waterflooding. Disposal typically involves fluid injection through old and potentially corroded boreholes and does not include monitoring to the same extent as waterflooding. Such fluid injection could affect the performance of the disposal system if sufficient fluid leaked into the Salado interbeds to affect the rate of brine flow into the waste disposal panels.

Stoelzel and O'Brien (1996) evaluated the potential effects on the disposal system of leakage from a hypothetical salt water disposal borehole near the WIPP. Stoelzel and O'Brien (1996) used the two-dimensional BRAGFLO model (vertical north-south cross-section) to simulate saltwater disposal to the north and to the south of the disposal system. The disposal system model included the waste disposal region, the marker beds and anhydrite intervals near the excavation horizon, and the rock strata associated with local oil and gas developments. A worst case simulation was run using high values of borehole and anhydrite permeability and a low value of halite permeability to encourage flow to the disposal panels via the anhydrite. Also, the boreholes were assumed to be plugged immediately above the Salado (consistent with the plugging configurations described in Section 6.4.7.2). Values of key parameters for this simulation are shown in Table SCR-4.

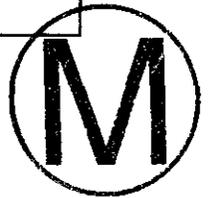

Saltwater disposal into the Upper Bell Canyon was simulated, with annular leakage through the Salado. A total of approximately  $7 \times 10^5$  cubic meters of brine was injected through the boreholes during a 50-year simulated disposal period. In this time, approximately 50 cubic meters of brine entered the anhydrite interval at the horizon of the waste disposal region. For the next 200 years the boreholes were assumed to be abandoned (with open-hole permeabilities of  $1 \times 10^{-9}$  square meters). Cement plugs (of permeability  $10^{-17}$  cubic meters) were assumed to be placed at the injection interval and at the top of the Salado. Subsequently, the boreholes were prescribed the permeability of silty sand (see Section 6.4.7.2), and the simulation was continued until the end of the 10,000-year regulatory period. During this period, approximately 400 cubic meters of brine entered the waste disposal region from the anhydrite interval. This value of cumulative brine inflow is within the bounds of the values generated by performance assessment calculations for the undisturbed scenario. During the disposal well simulation, leakage from the injection boreholes is likely to have had no significant effect on the inflow rate at the waste panels.

Thus, the hydraulic effects of leakage through historical, current, and near-future boreholes outside the controlled area have been eliminated from performance assessment calculations on the basis of low consequence to the performance of the disposal system.

1 **Table SCR-4. Parameters and Values Used in Screening the Effects of Water Flooding**  
 2

3 <b>Parameter</b>	<b>Value</b>
4 Halite permeability	$1.8 \times 10^{-25}$ square meters
5 Anhydrite permeability	$7.9 \times 10^{-18}$ square meters
6 Effective permeability of leaking borehole	$1.0 \times 10^{-11}$ square meters
7 Injection depth	4,260 feet (1,300 meters)
8 Bottomhole injection pressure	$3.3 \times 10^3$ pounds per square inch ( $23 \times 10^6$ pascals)
9 Injection pressure gradient	0.78 pounds per square inch per foot ( $1.8 \times 10^4$ pascals per meter)

10  
 11  
 12  
 13 *Effects of density changes resulting from leakage through injection boreholes*

14  
 15 Leakage through a failed borehole casing during a fluid injection operation in the vicinity of  
 16 the WIPP could alter fluid density in the affected unit, which could result in changes in fluid  
 17 flow rates and directions within the disposal system. Disposal of oil and gas production by-  
 18 products through boreholes could increase fluid densities in transmissive units affected by  
 19 leakage in the casing. Operations such as waterflooding use fluids derived from the target  
 20 reservoir, or fluids with a similar composition, to avoid scaling and other reactions.  
 21 Therefore, the effects of leakage from waterflood boreholes would be similar to leakage from  
 22 disposal wells.

23  
 24 Denser fluids have a tendency to sink relative to less dense fluids, and, if the hydrogeological  
 25 unit concerned has a dip, there will be a tendency for the dense fluid to travel in the downdip  
 26 direction. If this direction is the same as the direction of the groundwater pressure gradient,  
 27 there would be an increase in flow velocity, and conversely, if the downdip direction is  
 28 opposed to the direction of the groundwater pressure gradient, there would be a decrease in  
 29 flow velocity. In general terms, taking account of density-related flow will cause a rotation of  
 30 the flow vector towards the downdip direction that is dependent on the density contrast and  
 31 the dip.

32  
 33 Wilmot and Galson (1996) showed that brine density changes in the Culebra resulting from  
 34 leakage through an injection borehole outside the controlled area will not affect fluid flow in  
 35 the Culebra significantly. Potash mining activities assumed on the basis of regulatory criteria  
 36 to occur in the near future outside the controlled area will have a more significant effect on  
 37 modeled Culebra hydrology. The distribution of existing leases suggests that near-future  
 38 mining will take place to the north, west, and south of the controlled area (see Section  
 39 2.3.1.1). The effects of such potash mining are accounted for in calculations of undisturbed  
 40 performance of the disposal system (through an increase in the transmissivity of the Culebra  
 41 above the mined region, as discussed in Section SCR.3.3.2). Groundwater modeling that

1 accounts for potash mining shows a change in the fluid pressure distribution, and a consequent  
 2 shift of flow directions towards the west in the Culebra within the controlled area (Wallace  
 3 1996c). A localized increase in fluid density in the Culebra resulting from leakage from an  
 4 injection borehole would rotate the flow vector towards the downdip direction (towards the  
 5 east).

6  
 7 Wilmot and Galson (1996) compared the relative magnitudes of the freshwater head gradient  
 8 and the gravitational gradient and showed that the density effect is of low consequence to the  
 9 performance of the disposal system. According to Darcy's Law, flow in an isotropic porous  
 10 medium is governed by the gradient of fluid pressure and a gravitational term

$$\bar{v} = -\frac{k}{\mu} [\nabla p - \rho \bar{g}] ,$$

11 where

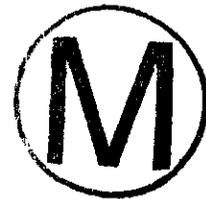

- 12  
 13  
 14  
 15  
 16  
 17  $\bar{v}$  = Darcy velocity vector (m s<sup>-1</sup>)  
 18  $k$  = intrinsic permeability (m<sup>2</sup>)  
 19  $\mu$  = fluid viscosity (pa s)  
 20  $\nabla p$  = gradient of fluid pressure (pa m<sup>-1</sup>)  
 21  $\rho$  = fluid density (kg m<sup>-3</sup>)  
 22  $\bar{g}$  = gravitational acceleration vector (m s<sup>-2</sup>)  
 23

24 The relationship between the gravity-driven flow component and the pressure-driven  
 25 component can be shown by expressing the velocity vector in terms of a freshwater head  
 26 gradient and a density-related elevation gradient

$$\bar{v} = -K [\nabla H_f + \frac{\Delta\rho}{\rho_f} \nabla E] ,$$

27 where

- 28  
 29  
 30  
 31  
 32  
 33  $K$  = hydraulic conductivity (m s<sup>-1</sup>)  
 34  $\nabla H_f$  = gradient of freshwater head  
 35  $\Delta\rho$  = difference between actual fluid  
 36 density and reference fluid density (kg m<sup>-3</sup>)  
 37  $\rho_f$  = density of freshwater (kg m<sup>-3</sup>)  
 38  $\nabla E$  = gradient of elevation  
 39

40 Davies (1989, 28) defined a driving force ratio (DFR) to assess the potential significance of  
 41 the density gradient

$$DFR = \frac{\Delta\rho |\nabla E|}{\rho_f |\nabla H_f|}$$

1 and concluded that a DFR of 0.5 can be considered an approximate threshold at which  
2 density-related gravity effects may become significant (Davies 1989, 28).

3  
4 The dip of the Culebra in the vicinity of the WIPP is about 0.44° or 8 meters per kilometer to  
5 the east (Davies 1989, 42). According to Davies (1989, 47 – 48), freshwater head gradients in  
6 the Culebra between the waste panels and the southwestern and western boundaries of the  
7 accessible environment range from 4 meters per kilometer to 7 meters per kilometer, with  
8 only small changes in gradient arising from the calculated effects of near-future mining.  
9 Culebra brines have densities ranging from 1,050 to 1,100 kilograms per cubic meter (Davies  
10 1989, 32). Assuming the density of fluid leaking from a waterflood borehole or a disposal  
11 well to be 1,215 kilograms per cubic meter (a conservative high value similar to the density of  
12 Castile brine [Popielak et al. 1983, Table C-2]), leads to a DFR of between 0.13 and 0.38.  
13 These values of the DFR show that density-related effects caused by leakage of brine into the  
14 Culebra during fluid injection operations are not significant.

15  
16 In summary, the effects of historical, current, and near-future fluid injection (liquid waste  
17 disposal, enhanced oil and gas production, and hydrocarbon storage) through boreholes  
18 outside the controlled area have been eliminated from performance assessment calculations on  
19 the basis of low consequence to the performance of the disposal system.

20  
21 *Geochemical effects of leakage through injection boreholes*

22  
23 Injection of fluids through a leaking borehole could affect the geochemical conditions in thief  
24 zones, such as the Salado interbeds or the Culebra. Such **fluid injection-induced**  
25 **geochemical changes** could alter radionuclide migration rates within the disposal system in  
26 the affected units if they occur sufficiently close to the edge of the controlled area through  
27 their effects on colloid transport and sorption.

28  
29 The majority of fluids injected (for example, during brine disposal) have been extracted  
30 locally during production activities. Because they have been derived locally, their  
31 compositions are similar to fluids currently present in the disposal system, and they will have  
32 low total colloid concentrations compared to those in the waste disposal panels (see Section  
33 SCR.3.3.1.1.1). The repository will remain the main source of colloids in the disposal system.  
34 Therefore, colloid transport as a result of historical, current, and near-future fluid injection has  
35 been eliminated from performance assessment calculations on the basis of low consequence to  
36 the performance of the disposal system.

37  
38 As discussed in Section SCR.3.3.1.1.1, sorption within the Culebra is accounted for in  
39 performance assessment calculations. The sorption model used accounts for the effects of any  
40 changes in sorption in the Culebra as a result of leakage through historical, current, and near-  
41 future injection boreholes.

42  
43 Consistent with the screening discussion in Section SCR.3.3.1.1.1, the effects of changes in  
44 sorption in the Dewey Lake within the controlled area as a result of leakage through historical,

1 current, and near-future injection boreholes have been eliminated from performance  
2 assessment calculations on the basis of low consequence to the performance of the disposal  
3 system. Sorption within other geological units of the disposal system has been eliminated  
4 from performance assessment calculations on the basis of beneficial consequence to the  
5 performance of the disposal system.

6  
7 Nonlocally derived fluids could be used during hydraulic fracturing operations. However,  
8 such fluid injection operations would be carefully controlled to minimize leakage to thief  
9 zones. Therefore, any potential geochemical effects of such leakages have been eliminated  
10 from performance assessment calculations on the basis of low consequence to the  
11 performance of the disposal system.

12  
13 *SCR.3.3.1.3.2 Future Human-Initiated EPs*

14  
15 Consistent with 40 CFR § 194.33(d), performance assessments need not analyze the effects of  
16 techniques used for resource recovery subsequent to the drilling of a future borehole. **Liquid**  
17 **waste disposal** (by-products from oil and gas production), **enhanced oil and gas production**,  
18 and **hydrocarbon storage** are techniques associated with resource recovery. Therefore, the  
19 use of future boreholes for such activities and **fluid injection-induced geochemical changes**  
20 have been eliminated from performance assessment calculations on regulatory grounds.

21  
22 *SCR.3.3.1.4 Flow Through Abandoned Boreholes*

23  
24 *The effects of natural fluid flow through existing or near-future abandoned boreholes have*  
25 *been eliminated from performance assessment calculations on the basis of low consequence to*  
26 *the performance of the disposal system. Flow through undetected boreholes within or outside*  
27 *the controlled area has been eliminated from performance assessment calculations on the*  
28 *basis of low probability of occurrence of such boreholes. Waste-induced flow through*  
29 *boreholes drilled in the near future has been eliminated from performance assessment*  
30 *calculations on regulatory grounds. Waste-induced borehole flow and natural borehole flow*  
31 *through a future borehole that intersects a waste panel are accounted for in performance*  
32 *assessment calculations. The effects of natural borehole flow through a future borehole that*  
33 *does not intersect the waste-disposal region have been eliminated from performance*  
34 *assessment calculations on the basis of low consequence to the performance of the disposal*  
35 *system. Geochemical changes that occur inside the controlled area as a result of long-term*  
36 *flow associated with historical, current, near-future, and future abandoned boreholes are*  
37 *accounted for in performance assessment calculations. The effects of borehole-induced*  
38 *solution and subsidence, and mineralization, associated with existing, near-future, and future*  
39 *abandoned boreholes have been eliminated from performance assessment calculations on the*  
40 *basis of low consequence to the performance of the disposal system.*

41  
42 Abandoned boreholes could provide pathways for fluid flow and, potentially, contaminant  
43 transport between any intersected zones. For example, such boreholes could provide

1 pathways for vertical flow between transmissive units in the Rustler, or between the Culebra  
2 and units below the Salado, which could affect fluid densities, flow rates, and flow directions.

3  
4 Movement of fluids through abandoned boreholes could result in borehole-induced  
5 geochemical changes in the receiving units such as the Salado interbeds or Culebra, and thus  
6 alter radionuclide migration rates in these units.

7  
8 Potentially, boreholes could provide pathways for surface-derived water or groundwater to  
9 percolate through low-permeability strata and into formations containing soluble minerals.  
10 Large-scale dissolution through this mechanism could lead to subsidence and to changes in  
11 groundwater flow patterns. Also, fluid flow between hydraulically conductive horizons  
12 through a borehole may result in changes in permeability in the affected units through mineral  
13 precipitation.

14  
15 *SCR.3.3.1.4.1 Historical, Current, and Near-Future Human-Initiated EPs*

16  
17 Abandoned water, potash, oil, and gas exploration and production boreholes exist within and  
18 outside the controlled area. The DOE assumes that records of past and present drilling  
19 activities in New Mexico are accurate and that evidence of any preexisting boreholes would  
20 be included in these records. In addition, during site selection for the WIPP, the DOE  
21 searched for evidence of boreholes and found no previously unknown holes. Even if  
22 undetected boreholes did exist, their effects on the performance of the disposal system would  
23 be insignificant, according to arguments similar to those presented below for flow through  
24 abandoned boreholes. However, **flow through undetected boreholes** within or outside the  
25 controlled area has been eliminated from performance assessment calculations on the basis of  
26 low probability of occurrence of such boreholes.

27  
28 Continued resource exploration and production in the near future will result in the occurrence  
29 of many more abandoned boreholes in the vicinity of the controlled area. Institutional  
30 controls will prevent drilling (other than that associated with the WIPP development) from  
31 taking place within the controlled area in the near future. Therefore, no boreholes will  
32 intersect the waste disposal region in the near future, and **waste-induced borehole flow** in the  
33 near future has been eliminated from performance assessment calculations on regulatory  
34 grounds.

35  
36 *Hydraulic effects of flow through abandoned boreholes*

37  
38 **Natural borehole flow** through existing or near-future abandoned boreholes within or outside  
39 the controlled area could alter fluid pressure distributions within the disposal system.

40  
41 Fluid flow and radionuclide transport within the Culebra could be affected if deep boreholes  
42 result in hydraulic connections between the Culebra and deep overpressurized or  
43 underpressurized units, or if boreholes provide interconnections for flow between shallow  
44 units. Wallace (1996a) analyzed the potential effects of interconnections between the Culebra

1 and deep units in the future within the controlled area (as discussed in Section SCR.3.3.1.4.2)  
2 and concluded that such interconnections could be eliminated from performance assessment  
3 calculations on the basis of low consequence. Also, shallow interconnections via boreholes  
4 within the controlled area have been eliminated from performance assessment calculations on  
5 the basis of low consequence (see Section SCR.3.3.1.4.2). Long-term flow through  
6 abandoned boreholes within the controlled area would have a greater impact on Culebra  
7 hydrology than such interconnections outside the controlled area. Thus, the effects of fluid  
8 flow through existing and near-future abandoned boreholes have been eliminated from  
9 performance assessment calculations on the basis of low consequence to the performance of  
10 the disposal system.

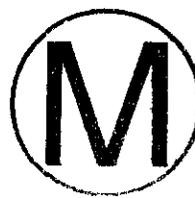

11 *Changes in fluid density resulting from flow through abandoned boreholes*

12  
13  
14 Leakage from historical, current, and near-future abandoned boreholes that penetrate  
15 pressurized brine pockets in the Castile could give rise to fluid density changes in affected  
16 units. Wilmot and Galson (1996) showed that brine density changes in the Culebra resulting  
17 from leakage through an abandoned borehole would not have a significant effect on the  
18 Culebra flow field. The effects on Culebra hydrology of potash mining activities expected to  
19 occur in the near-future outside the controlled area are likely to be more significant. The  
20 effects of mining are accounted for in calculations of undisturbed performance of the disposal  
21 system (through an increase in the transmissivity of the Culebra above the mined region, as  
22 discussed in Section SCR.3.3.2). Groundwater modeling that accounts for potash mining  
23 shows a change in the fluid pressure distribution and a consequent shift of flow directions  
24 towards the west in the Culebra within the controlled area (Wallace 1996c). A localized  
25 increase in fluid density in the Culebra resulting from leakage from an abandoned borehole  
26 would rotate the flow vector towards the downdip direction (towards the east). A comparison  
27 of the relative magnitudes of the freshwater head gradient and the gravitational gradient, based  
28 on an analysis similar to that presented in Section SCR.3.3.1.3, shows that the density effect is  
29 of low consequence to the performance of the disposal system.

30  
31 *Geochemical effects of borehole flow*

32  
33 Movement of fluids through abandoned boreholes could result in **borehole-induced**  
34 **geochemical changes** in the receiving units such as the Salado interbeds or Culebra. Such  
35 geochemical changes could alter radionuclide migration rates within the disposal system in the  
36 affected units if they occur sufficiently close to the edge of the controlled area, or if they occur  
37 as a result of flow through existing boreholes within the controlled area through their effects  
38 on colloid transport and sorption.

39  
40 The contents of the waste disposal panels provide the main source of colloids in the disposal  
41 system. Thus, consistent with the discussion in Section SCR.3.3.1.1.1, colloid transport as a  
42 result of flow through existing and near-future abandoned boreholes has been eliminated from  
43 performance assessment calculations on the basis of low consequence to the performance of  
44 the disposal system.

1 As discussed in Section SCR.3.3.1.1.1, sorption within the Culebra is accounted for in  
2 performance assessment calculations. The sorption model used accounts for the effects of  
3 changes in sorption in the Culebra as a result of flow through existing and near-future  
4 abandoned boreholes.

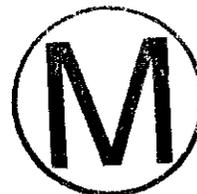

5  
6 Consistent with the screening discussion in Section SCR.3.3.1.1.1, the effects of changes in  
7 sorption in the Dewey Lake inside the controlled area as a result of flow through existing and  
8 near-future abandoned boreholes have been eliminated from performance assessment  
9 calculations on the basis of low consequence to the performance of the disposal system.  
10 Sorption within other geological units of the disposal system has been eliminated from  
11 performance assessment calculations on the basis of beneficial consequence to the  
12 performance of the disposal system.

13  
14 *Borehole-induced solution and subsidence*

15  
16 Three features are required for significant **borehole-induced solution and subsidence** to  
17 occur through downward percolation of freshwater: a borehole, an energy gradient to drive  
18 freshwater downward through underlying brines to the Salado, and a sink or conduit to allow  
19 migration of brine away from the site of dissolution. Without these features, minor  
20 dissolution in the immediate vicinity of a borehole could occur, but percolating water would  
21 become saturated and prevent further dissolution.

22  
23 An example of borehole-induced dissolution and subsidence occurred about 100 miles (160  
24 kilometers) southeast of the WIPP site (outside the Delaware Basin) at the Wink Sink  
25 (Johnson 1987); percolation of shallow groundwater through abandoned boreholes,  
26 dissolution of the Salado, and subsidence of overlying units led to a surface collapse feature  
27 360 feet (110 meters) in width and 110 feet (34 meters) deep. At Wink Sink, the Salado is  
28 underlain by the Tansill, Yates, and Capitan Formations, which contain vugs and solution  
29 cavities through which brine could migrate. Also, the hydraulic head of the Santa Rosa (the  
30 uppermost aquifer) is greater than those of the deep aquifers (Tansill, Yates, and Capitan  
31 Formations), suggesting downward flow if a connection were established.

32  
33 The size of the dissolution cavity that caused Wink Sink is not known, but the size of the  
34 surface hollow suggests that, of existing boreholes that penetrate below repository depth near  
35 the WIPP, only ERDA-9 (see Chapter 2.0, Figure 2-2) is close enough to the repository to be  
36 of concern. Sealing of WIPP investigation boreholes (discussed in Chapter 3.0) and plugging  
37 of oil and gas boreholes (see Appendix DEL) will, to some extent, reduce the potential for  
38 borehole-induced solution and subsidence. However, corrosion of the well casing over the  
39 long term could allow percolation of surface-derived and shallow-formation waters into the  
40 borehole. Even if extensive seals are emplaced, casing corrosion could still allow a flow path  
41 to develop in strata where salt creep is not active. However, the bottom of ERDA-9 is in the  
42 Castile, just below the Salado. No sink exists at such a depth for downward percolation of  
43 water to persist.

1 Beauheim (1986) considered the direction of natural fluid flow through boreholes in the  
2 vicinity of the WIPP. Beauheim (1986, 72) examined hydraulic heads measured using drill  
3 stem tests in the Bell Canyon and the Culebra at well DOE-2 and concluded that the direction  
4 of flow in a cased borehole open only to the Bell Canyon and the Culebra would be upward.  
5 However, dissolution of halite in the Castile and the Salado would increase the relative  
6 density of the fluid in an open borehole, causing a reduction in the rate of upward flow.  
7 Potentially, the direction of borehole fluid flow could reverse, but such a flow could be  
8 sustained only if sufficient driving pressure, porosity, and permeability exist for fluid to flow  
9 laterally within the Bell Canyon. A further potential sink for Salado-derived brine is the  
10 Capitan Limestone. However, the subsurface extent of the Capitan Reef is approximately 10  
11 miles (16 kilometers) from the WIPP at its closest point, and this unit will not provide a sink  
12 for brine derived from boreholes in the vicinity of the controlled area. A similar screening  
13 argument is made for natural deep dissolution in the vicinity of the WIPP (see Section  
14 SCR.1.1.5.1.). Thus, the effects of borehole-induced solution and subsidence around existing  
15 abandoned boreholes, and boreholes drilled and abandoned in the near-future, have been  
16 eliminated from performance assessment calculations on the basis of low consequence to the  
17 performance of the disposal system.

18  
19 *Borehole-induced mineralization*

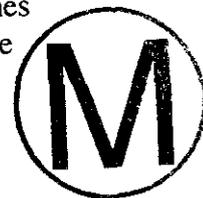

20  
21 Fluid flow between hydraulically conductive horizons through a borehole may result in  
22 changes in permeability in the affected units through mineral precipitation. For example:

- 23  
24 • Limited calcite precipitation may occur as the waters mix in the Culebra immediately  
25 surrounding the borehole, and calcite dissolution may occur as the brines migrate away  
26 from the borehole due to variations in water chemistry along the flow path.  
27  
28 • Gypsum may be dissolved as the waters mix in the Culebra immediately surrounding  
29 the borehole but may precipitate as the waters migrate through the Culebra.  
30

31 The effects of these mass transfer processes on groundwater flow depend on the original  
32 permeability structure of the Culebra rocks and the location of the mass transfer. The volumes  
33 of minerals that may precipitate and/or dissolve in the Culebra as a result of the injection of  
34 Castile or Salado brine through a borehole will not affect the existing spatial variability in the  
35 permeability field significantly. Consequently, the effects of **borehole-induced**  
36 **mineralization** on permeability and groundwater flow within the Culebra, as a result of brines  
37 introduced via any existing abandoned boreholes, and boreholes drilled and abandoned in the  
38 near-future, have been eliminated from performance assessment calculations on the basis of  
39 low consequence to the performance of the disposal system.

40  
41 *SCR.3.3.1.4.2 Future Human-Initiated EPs*

42  
43 The EPA provides criteria concerning analysis of the consequences of future drilling events in  
44 40 CFR § 194.33(c). Consistent with these criteria, the DOE assumes that after drilling is

1 complete the borehole is plugged according to current practice in the Delaware Basin (see  
2 Section 6.4.7.2). Degradation of casing and/or plugs may result in connections for fluid flow  
3 and, potentially, contaminant transport between connected hydraulically conductive zones.  
4 The long-term consequences of boreholes drilled and abandoned in the future will primarily  
5 depend on the location of the borehole and the borehole casing and plugging methods used.

6  
7 *Hydraulic effects of flow through abandoned boreholes*

8  
9 An abandoned future borehole that intersects a waste panel could provide a connection for  
10 contaminant transport away from the repository horizon. If the borehole has degraded casing  
11 and/or plugs, and the fluid pressure within the waste panel is sufficient, radionuclides could be  
12 transported to the land surface. Additionally, if brine flows through the borehole to overlying  
13 units, such as the Culebra, it may carry dissolved and colloidal actinides that can be  
14 transported laterally to the accessible environment by natural groundwater flow in the  
15 overlying units. Long-term **waste-induced borehole flow** is accounted for in performance  
16 assessment calculations (see Section 6.4.7.2).

17  
18 The units intersected by a future borehole that intersects a waste panel may provide sources or  
19 sinks for long-term fluid flow to or from the waste panel. For example, penetration of an  
20 underpressurized unit underlying the Salado could result in long-term downward flow and  
21 radionuclide transport from the waste panel to the underlying unit. The permeabilities of  
22 formations underlying the Salado are less than the permeability of the Culebra (Wallace  
23 1996a). Thus, under similar driving forces, fluids would migrate more rapidly through the  
24 Culebra than through units underlying the Salado. The consequences associated with  
25 radionuclide transport to an underpressurized unit below the waste panels are likely to be less  
26 significant, in terms of disposal system performance, than the consequences associated with  
27 radionuclide transport to the land surface or to the Culebra. Through this comparison,  
28 radionuclide transport to underpressurized units below the waste-disposal region has been  
29 eliminated from performance assessment calculations on the basis of low consequence to the  
30 performance of the disposal system.

31  
32 A future borehole that penetrates a Castile brine reservoir could provide a connection for brine  
33 flow from the reservoir to the waste panel, thus increasing fluid pressure and brine volume in  
34 the waste panel. Long-term **natural borehole flow** through such a borehole is accounted for  
35 in performance assessment calculations (see Section 6.4.8).

36  
37 Deep abandoned boreholes that intersect the Salado interbeds near the waste disposal panels  
38 could provide pathways for long-term radionuclide transport from the waste panels to the land  
39 surface or to overlying units. The potential significance of such events were assessed by  
40 WIPP Performance Assessment Division (1991, B-26 to B-27), which examined single-phase  
41 flow and transport between the waste panels and a borehole intersecting MB139 outside the  
42 DRZ. The analysis assumed an in situ pressure of 11 megapascals in MB139, a borehole  
43 pressure of 6.5 megapascals (hydrostatic) at MB139, and a constant pressure of 18  
44 megapascals as a source term in the waste panels representing gas generation. Also, MB139

1 was assigned a permeability of approximately  $3 \times 10^{-20}$  square meters and a porosity of 0.01  
2 percent. The disturbed zone was assumed to exist in MB139 directly beneath the repository  
3 only and was assigned a permeability of  $1.0 \times 10^{-17}$  square meters and a porosity of 0.055  
4 percent. Results showed that the rate of flow through a borehole located just 0.25 meters  
5 outside the DRZ would be more than two orders of magnitude less than the rate of flow  
6 through a borehole located within the DRZ because of the contrast in permeability. Thus, any  
7 releases of radionuclides to the accessible environment through deep boreholes that do not  
8 intersect waste panels would be insignificant compared to the releases that would result from  
9 transport through boreholes that intersect waste panels. Thus, radionuclide transport through  
10 deep boreholes that do not intersect waste panels has been eliminated from performance  
11 assessment calculations on the basis of low consequence to the performance of the disposal  
12 system.

13  
14 Fluid flow and radionuclide transport within the Culebra could be affected if future deep  
15 boreholes result in hydraulic connections between the Culebra and deep overpressurized or  
16 underpressurized units. Over the 10,000-year regulatory period, a large number of deep  
17 boreholes could be drilled within and around the controlled area (see Section 6.4.12.2). The  
18 effects on the performance of the disposal system of long-term hydraulic connections between  
19 the Culebra and deep units depends on the location of the boreholes. In some cases, changes  
20 in the Culebra flow field caused by interconnections with deep units could increase lateral  
21 radionuclide travel times to the accessible environment.

22  
23 As part of an analysis to determine the impact of such interconnections, Wallace (1996a)  
24 gathered information on the pressures, permeabilities, and thicknesses of potential oil- or gas-  
25 bearing sedimentary units; such units exist to a depth of about 18,000 feet (5,500 meters) in  
26 the vicinity of the WIPP. Of these units, the Atoka Unit, some 13,100 feet (4,000 meters)  
27 below the land surface, has the highest documented pressure of about 9,300 pounds per square  
28 inch ( $64 \times 10^6$  pascals), with permeabilities of about  $2 \times 10^{-14}$  square meters. The Strawn  
29 Unit, 12,800 feet (3,900 meters) below the land surface, has the lowest pressures (5,000  
30 pounds per square inch [ $35 \times 10^6$  pascals], which is lower than hydrostatic) and highest  
31 permeability ( $10^{-13}$  square meters) of the deep units. Thus, in order to assess the maximum  
32 potential impact of interconnections between deep units and the Culebra, Wallace (1996a)  
33 evaluated the effects of long-term flow through boreholes from the Atoka to the Culebra  
34 (source) and from the Culebra to the Strawn (sink). Although the Atoka is primarily a gas-  
35 bearing unit, Wallace (1996a) conservatively assumed that the unit is brine saturated; in the  
36 long term, gas from the Atoka would most likely flow through a borehole to the land surface  
37 and would not affect the Culebra significantly.

38  
39 Performance assessment calculations indicate that the shortest radionuclide travel times to the  
40 accessible environment through the Culebra occur when flow in the Culebra in the disposal  
41 system is from north to south. Wallace (1996a) ran the steady-state SECOFL2D model with  
42 the performance assessment data that generated the shortest radionuclide travel times (with  
43 and without mining in the controlled area) but perturbed the flow field by placing a brine  
44 source borehole in the Culebra just north of the waste disposal panels and a sink borehole just

1 south of the controlled area. The fluid flux through each borehole was determined using  
2 Darcy's Law, assuming a borehole hydraulic conductivity of  $10^{-4}$  meter per second (for a  
3 permeability of about  $10^{-11}$  square meters), a borehole radius of 0.8 feet (0.25 meters), and a  
4 fluid pressure in the Culebra of 1,790 pounds per square inch ( $12.3 \times 10^6$  pascals) at a depth of  
5 about 650 feet (200 meters). Thus, the Atoka was assumed to transmit brine to the Culebra at  
6 about  $1.4 \times 10^{-5}$  cubic meters per second, and the Strawn was assumed to receive brine from  
7 the Culebra at about  $1.5 \times 10^{-6}$  cubic meters per second.

8  
9 Travel times through the Culebra to the accessible environment were calculated using the  
10 SECOFL2D velocity fields for particles released to the Culebra above the waste panels,  
11 assuming no retardation by sorption or diffusion into the rock matrix. Mean Darcy velocities  
12 were then determined from the distance each radionuclide travelled, the time taken to reach  
13 the accessible environment, and the effective Culebra porosity. The results show that, at  
14 worst, interconnections between the Culebra and deep units could cause a doubling of the  
15 largest mean Darcy velocity expected in the Culebra in the absence of such interconnections.

16  
17 Performance assessment calculations show that radionuclide retardation in the Culebra limits  
18 lateral migration of radionuclides to just a few hundred meters in the 10,000-year regulatory  
19 time frame. A doubling of the Darcy velocity would cause only a minor increase in the lateral  
20 extent of radionuclide migration through the Culebra and would not lead to any radionuclide  
21 releases to the accessible environment in the regulatory time frame. Thus, the effects of fluid  
22 flow through a future deep abandoned borehole that does not intersect the waste disposal  
23 region have been eliminated from performance assessment calculations on the basis of low  
24 consequence to the performance of the disposal system.

25  
26 Future abandoned boreholes could also provide interconnections for long-term fluid flow  
27 between shallow units (overlying the Salado). In particular, abandoned boreholes could  
28 provide pathways for downward flow of water from the Magenta to the Culebra; the Culebra  
29 hydraulic head is lower than the Tamarisk hydraulic head and these units are hydraulically  
30 isolated from each other by the relatively low permeability Tamarisk. If a large number of  
31 such boreholes were to occur in and around the controlled area in the future, they could result  
32 in an effective increase in vertical hydraulic conductivity in the Tamarisk. On the basis of  
33 three-dimensional groundwater flow modeling, Corbet (1995) determined that an increase in  
34 vertical hydraulic conductivity in the Tamarisk would result in a reduction in hydraulic head  
35 in the Magenta and an increase in hydraulic head in the Culebra, although there would be little  
36 change in the magnitude of the horizontal hydraulic head gradient in the Culebra. However,  
37 the change in the Culebra hydraulic head would be accompanied by a change in flow direction  
38 from north-south to northeast-southwest within the controlled area. Culebra hydraulic  
39 conductivities to the southwest of the waste panel region are two to three orders of magnitude  
40 lower than those to the south of the waste panel region. Therefore, the change in flow  
41 direction in the Culebra induced by connections to the Magenta would increase radionuclide  
42 travel times laterally through the Culebra to the accessible environment. Note that the  
43 Culebra hydraulic head would remain lower than the land surface and, therefore, radionuclides  
44 could not be transported vertically through boreholes to the accessible environment. Thus, a

1 large number of future borehole interconnections between shallow units would be beneficial  
2 to the long-term performance of the disposal system.

3  
4 The most likely conditions under which radionuclide travel times through the Culebra might  
5 decrease are those in which a specific configuration of boreholes caused the hydraulic head  
6 gradient in the Culebra to increase without changing the flow direction. This might be  
7 achieved if one or more future abandoned boreholes were to exist just north of the waste  
8 disposal region, providing a pathway for flow from the Magenta to the Culebra. The Culebra  
9 hydraulic head would be raised at this point. The increase in hydraulic head gradient caused  
10 by such an event would be less than that caused by long-term flow from a deep  
11 overpressurized unit such as the Atoka. As discussed above, flow to the Culebra from deep  
12 overpressurized units will be of low consequence to the performance of the disposal system.  
13 Thus, by comparison, the effects of a connection via a borehole between the Magenta and the  
14 Culebra have been eliminated from performance assessment calculations on the basis of low  
15 consequence to the performance of the disposal system.

16  
17 *Changes in fluid density resulting from flow through abandoned boreholes*

18  
19 A future borehole that intersects a pressurized brine reservoir in the Castile could also provide  
20 a source for brine flow to the Culebra in the event of borehole casing leakage, with a  
21 consequent localized increase in fluid density in the Culebra. The effect of such a change in  
22 fluid density would be to increase any gravity-driven component of groundwater flow. If the  
23 downdip direction, along which the gravity-driven component would be directed, is different  
24 to the direction of the groundwater pressure gradient, there would be a rotation of the flow  
25 vector towards the downdip direction. The groundwater modeling presented by Davies (1989,  
26 50) indicates that a borehole that intersects a pressurized brine pocket and causes a localized  
27 increase in fluid density in the Culebra above the waste panels would result in a rotation of the  
28 flow vector slightly towards the east. However, the magnitude of this effect would be small in  
29 comparison to the effects of the head gradient (see Section SCR.3.3.1.3), and such a localized  
30 increase in density would not divert radionuclides into the high-transmissivity zone within the  
31 Culebra.

32  
33 Over the 10,000-year regulatory period a large number of boreholes could be drilled within  
34 and around the controlled area (see Section 6.4.12.2). If sufficient of these boreholes intersect  
35 pressurized brine pockets and connect with the Culebra, density changes in the Culebra may  
36 become widespread.

37  
38 Gravity effects related to increase in density of Culebra groundwaters south of the waste  
39 panels will be small in comparison to freshwater head gradients (see Section SCR.3.3.1.3).  
40 The calculations undertaken by Davies (1989, 50) show that a density increase in the northern  
41 part of the controlled area could rotate the flow vector and hence affect flow in the region of  
42 the waste panels. However, these calculations did not consider any effects of mining on flow  
43 in the Culebra, and were based on a relatively flat pressure gradient in this region.  
44 Accounting for potash mining (through an increase in the transmissivity of the Culebra above

1 the mined region) results in a rotation of the freshwater head gradient towards the west (see  
2 Wallace, 1996c). Density-related gravity effects would oppose this gradient and increase  
3 travel times to the western boundary of the controlled area.

4  
5 *Geochemical effects of flow through abandoned boreholes*

6  
7 Movement of fluids through abandoned boreholes could result in **borehole-induced**  
8 **geochemical changes** in the receiving units, such as the Salado interbeds or Culebra. Such  
9 geochemical changes could alter radionuclide migration rates within the disposal system in the  
10 affected units through their effects on colloid transport and sorption.

11  
12 The waste disposal panels provide the main source of colloids in the disposal system. Colloid  
13 transport within the Culebra as a result of long-term flow associated with future abandoned  
14 boreholes that intersect the waste disposal region are accounted for in performance assessment  
15 calculations, as described in Sections 6.4.3.6 and 6.4.6.2.1. Consistent with the discussion in  
16 Section SCR.3.3.1.1.1, colloid transport as a result of flow through future abandoned  
17 boreholes that do not intersect the waste disposal region has been eliminated from  
18 performance assessment calculations on the basis of low consequence to the performance of  
19 the disposal system. The Culebra is the most transmissive unit in the disposal system and it is  
20 the most likely unit through which significant radionuclide transport could occur. Therefore,  
21 colloid transport in units other than the Culebra, as a result of flow through future abandoned  
22 boreholes, has been eliminated from performance assessment calculations on the basis of low  
23 consequence to the performance of the disposal system.

24  
25 As discussed in Section SCR.3.3.1.1.1, sorption within the Culebra is accounted for in  
26 performance assessment calculations. The sorption model accounts for the effects of changes  
27 in sorption in the Culebra as a result of flow through future abandoned boreholes.

28  
29 Consistent with the screening discussion in Section SCR.3.3.1.1.1, the effects of changes in  
30 sorption in the Dewey Lake within the controlled area as a result of flow through future  
31 abandoned boreholes have been eliminated from performance assessment calculations on the  
32 basis of low consequence to the performance of the disposal system. Sorption within other  
33 geological units of the disposal system has been eliminated from performance assessment  
34 calculations on the basis of beneficial consequence to the performance of the disposal system.

35  
36 *Borehole-induced solution and subsidence*

37  
38 The only conditions under which significant dissolution around future boreholes might occur  
39 are those in which such a borehole intersects the WIPP excavation. Following corrosion of  
40 the steel borehole casing and degradation of the borehole plug immediately above the Salado  
41 (see Section 6.4.7.2), the excavated region could provide a sink for downward flow of water  
42 from units overlying the Salado, resulting in dissolution of the borehole wall. Downward  
43 flow could only occur prior to the occurrence of significant gas generation, brine inflow, or  
44 creep closure in the disposal rooms, when the fluid pressure is less than hydrostatic pressure.

1 Dissolution will continue until fluid pressures in the disposal room reach hydrostatic and  
2 downward flow ceases.

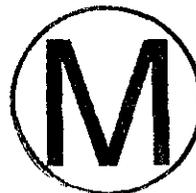

3  
4 Maximum dissolution, and maximum increase in borehole diameter, will occur at the top of  
5 the Salado; dissolution will decrease with depth as the percolating water becomes salt  
6 saturated. Eventually, degraded casing and concrete plug products, clays, and other materials  
7 will fill the borehole. Long-term flow through a borehole that intersects a waste panel is  
8 accounted for in disturbed performance calculations by assuming that the borehole is  
9 eventually filled by such materials, which have the properties of a silty sand (see Section  
10 6.4.7.2). However, these calculations assume that the borehole diameter does not increase  
11 with time.

12  
13 The potential extent of enlargement of a borehole that intersects a waste panel can be assessed  
14 given flow rates through the borehole and an estimate of the salt dissolution rate. The  
15 performance assessment calculations for an E2 drilling event at 1,000 years show a mean  
16 value of approximately  $2 \times 10^5$  cubic feet ( $5 \times 10^3$  cubic meters) of fluid flowing into the  
17 intersected waste panel through the borehole up to the end of the 10,000-year regulatory  
18 period. Assuming instantaneous dissolution of salt upon contact with freshwater, Christensen  
19 et al. (1983, 19) estimated that 0.2 cubic feet of salt are dissolved for every cubic foot of  
20 freshwater that flows through a borehole. Thus, if  $2 \times 10^5$  cubic feet ( $5 \times 10^3$  cubic meters) of  
21 water flow through the borehole, then approximately  $4 \times 10^4$  cubic feet ( $1 \times 10^3$  cubic meters)  
22 of salt around the borehole will be dissolved.

23  
24 The dimensions of a cavity resulting from borehole-induced dissolution can be estimated by  
25 assuming that the aspect ratio of such a cavity would be similar to the aspect ratio of the  
26 surface subsidence caused by dissolution at Wink Sink. The aspect ratio (depth and width) of  
27 the surface collapse at Wink Sink is 0.3 (see Section SCR.3.3.1.4.1). Assuming that the  
28 borehole-induced dissolution cavity is conical in shape, then a dissolution cavity of volume  
29  $4 \times 10^4$  cubic feet ( $1 \times 10^3$  cubic meters) will have a depth of approximately 20 feet (6 meters)  
30 and a diameter of approximately 65 feet (20 meters). The salt between the waste panel and  
31 the top of the Salado is approximately 1,250 feet (380 meters) thick. Thus, such dissolution  
32 will not affect the integrity of the majority of the salt above the waste panels, and it is unlikely  
33 to affect the rate of fluid flow through the borehole to the waste panel. The subsidence  
34 induced by such a cavity could result in an increase in hydraulic conductivity within the  
35 Culebra though increased vertical strain accompanied by fracture opening. However, the  
36 change in hydraulic conductivity within the Culebra from borehole-induced solution and  
37 subsidence will be restricted to the area above the waste panels, and will have no significant  
38 affect on the long-term performance of the disposal system.

39  
40 In summary, the effects of **borehole-induced solution and subsidence** around future  
41 abandoned boreholes have been eliminated from performance assessment calculations on the  
42 basis of low consequence to the performance of the disposal system.

43  
44 *Borehole-induced mineralization*

1 Fluid flow between hydraulically conductive horizons through a future borehole may result in  
2 changes in permeability in the affected units through mineral precipitation. However, the  
3 effects of mineral precipitation as a result of flow through a future borehole in the controlled  
4 area will be similar to the effects of mineral precipitation as a result of flow through an  
5 existing or near-future borehole (see Section SCR.3.3.1.4.1). Thus, **borehole-induced**  
6 **mineralization** associated with flow through a future borehole has been eliminated from  
7 performance assessment calculations on the basis of low consequence to the performance of  
8 the disposal system.

9  
10 SCR.3.3.2 Excavation-Induced Flow

11  
12 *Changes in groundwater flow due to historical, current, near-future, and future potash*  
13 *mining are accounted for in performance assessment calculations. Changes in geochemistry*  
14 *due to historical, current, and near-future potash mining have been eliminated from*  
15 *performance assessment calculations on the basis of low consequence to the performance of*  
16 *the disposal system. Changes in geochemistry due to future mining have been eliminated*  
17 *from performance assessment calculations on regulatory grounds.*

18  
19 Excavation activities may result in hydrological disturbances of the disposal system.  
20 Subsidence associated with excavations may affect groundwater flow patterns through  
21 increased hydraulic conductivity within and between units. Fluid flow associated with  
22 excavation activities may also result in changes in brine density and geochemistry in the  
23 disposal system.

24  
25 SCR.3.3.2.1 Historical, Current, and Near-Future Human-Initiated EPs

26  
27 As discussed in Section SCR.3.2.2, potash mining is the only excavation activity currently  
28 taking place in the vicinity of the WIPP that could affect hydrogeological or geochemical  
29 conditions in the disposal system. Potash is mined in the region east of Carlsbad and up to 3.1  
30 miles (5 kilometers) from the boundaries of the controlled area. Mining of the McNutt in the  
31 Salado is expected to continue in the vicinity of the WIPP (see Section 2.3.1.1): the DOE  
32 assumes that all economically recoverable potash in the vicinity of the WIPP (outside the  
33 controlled area) will be extracted in the near future.

34  
35 *Hydrogeological effects of mining*

36  
37 Potash mining in the Delaware Basin typically involves constructing vertical shafts to the  
38 elevation of the ore zone and then extracting the minerals in an excavation that follows the  
39 trend of the ore body. Potash has been extracted using conventional room and pillar mining,  
40 secondary mining where pillars are removed, and modified long-wall mining methods.  
41 Mining techniques used include drilling and blasting (used for mining langbeinite) and  
42 continuous mining (commonly used for mining sylvite). The DOE (Westinghouse 1994, 2-17  
43 to 2-19) reported investigations of subsidence associated with potash mining operations  
44 located near the WIPP. The reported maximum total subsidence at potash mines is about 5

1 feet (1.5 meters), representing up to 66 percent of initial excavation height, with an observed  
2 angle of draw from the vertical at the edge of the excavation of 58 degrees. The DOE  
3 (Westinghouse 1994, 2-22 to 2-23) found no evidence that subsidence over local potash mines  
4 had caused fracturing sufficient to connect the mining horizon to water-bearing units or the  
5 surface. However, subsidence associated with mining in the McNutt in the vicinity of the  
6 WIPP may affect the lateral hydraulic conductivity of overlying units, such as the Culebra,  
7 which could influence the direction and magnitude of fluid flow within the disposal system.  
8 Such **changes in groundwater flow due to mining** are accounted for in calculations of  
9 undisturbed performance of the disposal system (see Section 6.4.6.2.3).

10  
11 Potash mining, and the associated processing outside the controlled area, have changed fluid  
12 densities within the Culebra, as demonstrated by the areas of higher densities around  
13 boreholes WIPP-27 and WIPP-29 (Davies 1989, 43). Transient groundwater flow  
14 calculations (Davies 1989, 77 – 81) show that brine density variations to the west of the WIPP  
15 site caused by historical and current potash processing operations will not persist because the  
16 rate of groundwater flow in this area is fast enough to flush the high density groundwaters to  
17 the Pecos River. These calculations also show that accounting for the existing brine density  
18 variations in the region east of the WIPP site, where hydraulic conductivities are low, would  
19 have little effect on the direction or rate of groundwater flow. Therefore, changes in fluid  
20 densities from historical and current human-initiated EPs have been eliminated from  
21 performance assessment calculations on the basis of low consequence to the performance of  
22 the disposal system.

23  
24 The distribution of existing leases and potash grades suggests that near-future mining will take  
25 place to the north, west, and south of the controlled area (see Appendix DEL). Groundwater  
26 modeling that accounts for mining (through an increase in the transmissivity of the Culebra  
27 above the mined region) shows a change in the fluid pressure distribution, and a consequent  
28 shift of flow directions towards the west in the Culebra within the controlled area (Wallace,  
29 1996c). A localized increase in fluid density in the Culebra, in the mined region or elsewhere  
30 outside the controlled area, would rotate the flow vector towards the downdip direction  
31 (towards the east). A comparison of the relative magnitudes of the freshwater head gradient  
32 and the gravitational gradient (based on an analysis identical to that presented for fluid  
33 leakage to the Culebra through boreholes) shows that the density effect is of low consequence  
34 to the performance of the disposal system.

35  
36 *Geochemical effects of mining*

37  
38 Fluid flow associated with excavation activities may result in geochemical disturbances of the  
39 disposal system. Some waters from the Culebra reflect the influence of current potash mining,  
40 having elevated potassium to sodium ratios. However, potash mining has had no significant  
41 effect on the geochemical characteristics of the disposal system. Solution mining, which  
42 involves the injection of freshwater to dissolve the ore body, can be used for extracting  
43 sylvite. However, lack of availability of freshwater has resulted in limited use of this mining  
44 technique in the Delaware Basin, and solution mining is not expected to occur in the near

1 future in the vicinity of the WIPP site. Thus, **changes in geochemistry due to mining**  
2 (historical, current, and near-future) have been eliminated from performance assessment  
3 calculations on the basis of low consequence to the performance of the disposal system.  
4

5 *SCR.3.3.2.2 Future Human-Initiated EPs*  
6

7 Consistent with 40 CFR § 194.32(b), consideration of future mining may be limited to potash  
8 mining within the disposal system (see Section 3.3.2). Within the controlled area, the McNutt  
9 provides the only potash of appropriate quality. The extent of possible future potash mining  
10 within the controlled area is discussed in Section 2.3.1.1. Criteria concerning the consequence  
11 modeling of future mining are provided in 40 CFR § 194.32(b): the effects of future mining  
12 may be limited to changes in the hydraulic conductivity of the hydrogeologic units of the  
13 disposal system. Thus, consistent with 40 CFR § 194.32(b), **changes in groundwater flow**  
14 **due to mining** within the controlled area are accounted for in calculations of the disturbed  
15 performance of the disposal system (see Section 6.4.6.2.3). Other potential effects, such as  
16 **changes in geochemistry due to mining**, have been eliminated from performance assessment  
17 calculations on regulatory grounds.  
18

19 *SCR.3.3.3 Explosion-Induced Flow*  
20

21 *Changes in groundwater flow due to historical explosions have been eliminated from*  
22 *performance assessment calculations on the basis of low consequence to the performance of*  
23 *the disposal system. Changes in groundwater flow due to future explosions have been*  
24 *eliminated from performance assessment calculations on regulatory grounds.*  
25

26 This section discusses the potential hydrological disturbances of the disposal system that may  
27 occur as a result of explosions.  
28

29 *SCR.3.3.3.1 Historical, Current, and Near-Future Human-Initiated EPs*  
30

31 The small-scale explosions that have been used in the Delaware Basin to fracture oil- and  
32 natural-gas-bearing units to enhance resource recovery have been too deep to have disturbed  
33 the hydrology of the disposal system (see Section SCR.3.2.3.1).  
34

35 Also, as discussed in Section SCR.3.2.3.2, the Delaware Basin has been used for an isolated  
36 nuclear test (Project Gnome), approximately 8 miles (13 kilometers) southwest of the WIPP  
37 waste disposal region. An induced zone of increased permeability was observed to extend  
38 150 feet (46 meters) laterally from the point of the explosion. The increase in permeability  
39 was primarily associated with motions and separations along bedding planes, the major pre-  
40 existing weaknesses in the rock. This region of increased permeability is too far from the  
41 WIPP site to have had a significant effect on the hydrological characteristics of the disposal  
42 system. Thus, **changes in groundwater flow due to explosions** in the past have been  
43 eliminated from performance assessment calculations on the basis of low consequence to the  
44 performance of the disposal system.

1 *SCR.3.3.3.2 Future Human-Initiated EPs*

2  
3 The criterion in 40 CFR § 194.32(a), relating to the scope of performance assessments, limits  
4 the consideration of future human actions to mining and drilling. Also, consistent with  
5 40 CFR § 194.33(d), performance assessments need not analyze the effects of techniques used  
6 for resource recovery subsequent to the drilling of a future borehole. Therefore, **changes in**  
7 **groundwater flow due to explosions** in the future have been eliminated from performance  
8 assessment calculations on regulatory grounds.

9  
10 *SCR.3.4 Geomorphological EPs*

11  
12 *SCR.3.4.1 Land Use and Disturbances*

13  
14 *The effects of historical, current, and near-future surface disruptions have been eliminated*  
15 *from performance assessment calculations on the basis of low consequence to the*  
16 *performance of the disposal system. The effects of future surface disruptions have been*  
17 *eliminated from performance assessment calculations on regulatory grounds. Land use*  
18 *changes have been eliminated from performance assessment calculations on regulatory*  
19 *grounds.*

20  
21 This section discusses surface activities that could affect the geomorphological characteristics  
22 of the disposal system and result in changes in infiltration and recharge conditions. The  
23 potential effects of water use and control on disposal system performance are discussed in  
24 Section SCR.3.5.1.

25  
26 *SCR.3.4.1.1 Historical, Current, and Near-Future Human-Initiated EPs*

27  
28 Surface activities that take place at present in the vicinity of the WIPP site include those  
29 associated with potash mining, oil and gas reservoir development, water extraction, and  
30 grazing. Additionally, a number of archeological investigations have taken place within the  
31 controlled area that were aimed at protecting and preserving cultural resources. Elsewhere in  
32 the Delaware Basin, sand, gravel, and caliche are produced through surface quarrying.  
33 Although these activities have involved **surface disruptions** within the Delaware Basin, they  
34 have not altered the characteristics of the disposal system significantly, and they have  
35 therefore been eliminated from performance assessment calculations on the basis of low  
36 consequence to the performance of the disposal system. There are no existing plans for  
37 changes in land use in the vicinity of the WIPP in the near future. Therefore, consistent with  
38 the criteria in 40 CFR § 194.32(c) and 40 CFR § 194.54(b), **land use changes** in the near  
39 future in the vicinity of the WIPP have been eliminated from performance assessment  
40 calculations on regulatory grounds.

1 SCR.3.4.1.2 Future Human-Initiated EPs

2  
3 The criterion in 40 CFR § 194.25(a), concerned with predictions of the future states of society,  
4 requires that compliance assessments and performance assessments “shall assume that  
5 characteristics of the future remain what they are at the time the compliance application is  
6 prepared.” Therefore, future **land use changes** in the vicinity of the WIPP have been  
7 eliminated from performance assessment calculations on regulatory grounds.  
8

9 Criteria relating to future human activities in 40 CFR § 194.32(a) limit the scope of  
10 consideration of future human actions in performance assessments to mining and drilling.  
11 Therefore, the effects of future **surface disruptions** have been eliminated from performance  
12 assessment calculations on regulatory grounds.  
13

14 SCR.3.5 Surface Hydrological EPs

15  
16 SCR.3.5.1 Water Control and Use

17  
18 *The effects of historical, current, and near-future damming of streams and rivers, reservoirs,*  
19 *irrigation, and altered soil or surface water chemistry by human activities have been*  
20 *eliminated from performance assessment calculations on the basis of low consequence to the*  
21 *performance of the disposal system. Future damming of streams and rivers, reservoirs,*  
22 *irrigation, and altered soil or surface water chemistry by human activities have been*  
23 *eliminated from performance assessment calculations on regulatory grounds. The effects of*  
24 *lake usage have been eliminated from performance assessment calculations on regulatory*  
25 *grounds.*  
26

27 Irrigation and damming, as well as other forms of water control and use, could lead to  
28 localized changes in recharge, possibly leading to increased heads locally, thereby affecting  
29 flow directions and velocities in the Rustler and Dewey Lake. Surface activities, such as those  
30 associated with potash mining, could also affect soil and surface water chemistry. Note that  
31 the potential effects of geomorphological changes through land use are discussed in Section  
32 SCR.3.4.1.  
33

34 SCR.3.5.1.1 Historical, Current, and Near-Future Human-Initiated EPs

35  
36 In the WIPP area, two topographically low features, the Pecos River and Nash Draw, are  
37 sufficiently large to warrant consideration for damming. Dams and **reservoirs** already exist  
38 along the Pecos River. However, the Pecos River is far enough from the waste panels  
39 (12 miles [19 kilometers]) that the effects of **damming of streams and rivers** can be  
40 eliminated from performance assessment calculations on the basis of low consequence to the  
41 performance of the disposal system. Nash Draw is not currently dammed, and based on  
42 current hydrological and climatic conditions, there is no reason to believe it will be dammed  
43 in the near future.  
44

1 **Irrigation** uses water from rivers, lakes, impoundments, and wells to supplement the rainfall  
2 in an area to grow crops. Irrigation in arid environments needs to be efficient and involves the  
3 spreading of a relatively thin layer of water for uptake by plants, so little water would be  
4 expected to infiltrate beyond the root zone. However, some water added to the surface may  
5 infiltrate and reach the water table, affecting groundwater flow patterns. Irrigation currently  
6 takes place on a small scale within the Delaware Basin but not in the vicinity of the WIPP,  
7 and the extent of irrigation is not expected to change in the near future. Such irrigation has no  
8 significant effect on the characteristics of the disposal system. Thus, the effects of irrigation  
9 have been eliminated from performance assessment calculations on the basis of low  
10 consequence to the performance of the disposal system.

11  
12 Potash mining effluent and runoff from oil fields have altered soil and surface water chemistry  
13 in the vicinity of the WIPP. However, the performance of the disposal will not be sensitive to  
14 soil and surface water chemistry. Therefore, **altered soil or surface water chemistry by**  
15 **human activities** has been eliminated from performance assessment calculations on the basis  
16 of low consequence to the performance of the disposal system. The effects of effluent from  
17 potash processing on groundwater flow are discussed in Section SCR.3.3.2.

18  
19 Consistent with the criteria in 40 CFR § 194.32(c) and 40 CFR § 194.54(b), consideration of  
20 historical, current, and near-future human activities is limited to those activities that have  
21 occurred, or are expected to occur, in the vicinity of the disposal system. There are no large  
22 lakes in the vicinity of the WIPP and, therefore, human-initiated EPs related to **lake usage**  
23 have been eliminated from performance assessment calculations on regulatory grounds.

#### 24 25 *SCR.3.5.1.2 Future Human-Initiated EPs*

26  
27 The EPA has provided criteria relating to future human activities in 40 CFR § 194.32(a), that  
28 limit the scope of consideration of future human actions in performance assessments to  
29 mining and drilling. Therefore, the effects of future **damming of streams and rivers,**  
30 **reservoirs, irrigation, lake usage, and altered soil and surface water chemistry by human**  
31 **activities** have been eliminated from performance assessment calculations on regulatory  
32 grounds.

#### 33 34 *SCR.3.6 Climatic EPs*

##### 35 36 *SCR.3.6.1 Anthropogenic Climate Change*

37  
38 *The effects of anthropogenic climate change (acid rain, greenhouse gas effects, and damage*  
39 *to the ozone layer) have been eliminated from performance assessment calculations on*  
40 *regulatory grounds.*

41  
42 The effects of the current climate and natural climatic change are accounted for in  
43 performance assessment calculations, as discussed in Section SCR.6.4.9. However, human  
44 activities may also affect the future climate and thereby influence groundwater recharge in the

1 WIPP region. The effects of anthropogenic climate change may be on a local to regional scale  
2 (**acid rain**) or on a regional to global scale (**greenhouse gas effects** and **damage to the ozone**  
3 **layer**). Of these anthropogenic effects, only the greenhouse gas effect could influence  
4 groundwater recharge in the WIPP region. However, consistent with the future states  
5 assumptions in 40 CFR § 194.25(a), compliance assessments and performance assessments  
6 need not consider indirect anthropogenic effects on disposal system performance. Therefore,  
7 the effects of anthropogenic climate change have been eliminated from performance  
8 assessment calculations on regulatory grounds.

9  
10 **SCR.3.7 Marine EPs**

11  
12 **SCR.3.7.1 Marine Activities**

13  
14 *Historical, current, near-future, and future coastal water use, seawater use, and estuarine*  
15 *water use have been eliminated from performance assessment calculations on regulatory*  
16 *grounds.*

17  
18 This section discusses the potential for human-initiated EPs related to marine activities to  
19 affect infiltration and recharge conditions in the vicinity of the WIPP.

20  
21 **SCR.3.7.1.1 Historical, Current, and Near-Future Human-Initiated EPs**

22  
23 The WIPP site is more than 480 miles (800 kilometers) from the nearest seas, and  
24 hydrological conditions in the vicinity of the WIPP have not been affected by marine  
25 activities. Furthermore, consistent with the criteria in 40 CFR § 194.32(c) and 40 CFR  
26 § 194.54(b), consideration of historical, current, and near-future human activities is limited to  
27 those activities that have occurred or are expected to occur in the vicinity of the disposal  
28 system. Therefore, human-initiated EPs related to marine activities (such as **coastal water**  
29 **use, seawater use, and estuarine water use**) have been eliminated from performance  
30 assessment calculations on regulatory grounds.

31  
32 **SCR.3.7.1.2 Future Human-Initiated EPs**

33  
34 The EPA has provided criteria relating to future human activities in 40 CFR § 194.32(a) that  
35 limit the scope of consideration of future human actions in performance assessments to  
36 mining and drilling. Therefore, the effects of future marine activities (such as **coastal water**  
37 **use, seawater use, and estuarine water use**) have been eliminated from performance  
38 assessment calculations on regulatory grounds.

39  
40 **SCR.3.8 Ecological EPs**

41  
42 This section discusses the potential effects of agricultural activities and social and  
43 technological developments on the hydrogeology and geochemistry of the disposal system.

1 Ecological FEPs relating to plant, animal, soil, and human uptake of radionuclides are  
2 discussed in Section SCR.2.8.

3  
4 SCR.3.8.1 Agricultural Activities

5  
6 *The effects of historical, current, and near-future ranching and arable farming have been*  
7 *eliminated from performance assessment calculations on the basis of low consequence to the*  
8 *performance of the disposal system. The effects of changes in future ranching and arable*  
9 *farming practices have been eliminated from performance assessment calculations on*  
10 *regulatory grounds. Fish farming has been eliminated from performance assessment*  
11 *calculations on regulatory grounds.*

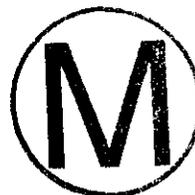

12  
13 Agricultural activities could affect infiltration and recharge conditions in the vicinity of the  
14 WIPP. Also, application of acids, oxidants, and nitrates during agricultural practice could  
15 alter groundwater geochemistry.

16  
17 SCR.3.8.1.1 Historical, Current, and Near-Future Human-Initiated EPs

18  
19 Grazing leases exist for all land sections immediately surrounding the WIPP and grazing  
20 occurs within the controlled area (see Section 2.3.2.2). Although grazing and related crop  
21 production have had some control on the vegetation at the WIPP site, these activities are  
22 unlikely to have affected subsurface hydrological or geochemical conditions. The climate,  
23 soil quality, and lack of suitable water sources all mitigate against agricultural development of  
24 the region in the near future. Therefore, the effects of historical, current, and near-future  
25 **ranching and arable farming** have been eliminated from performance assessment  
26 calculations on the basis of low consequence to the performance of the disposal system.  
27 Consistent with the criteria in 40 CFR § 194.32(c) and 40 CFR § 194.54(b), agricultural  
28 activities, such as **fish farming**, that have not taken place and are not expected to take place in  
29 the near future in the vicinity of the WIPP have been eliminated from performance assessment  
30 calculations on regulatory grounds.

31  
32 SCR.3.8.1.2 Future Human-Initiated EPs

33  
34 The EPA has provided criteria relating to future human activities in 40 CFR § 194.32(a), that  
35 limit the scope of consideration of future human activities in performance assessments to  
36 mining and drilling. Also, the criterion in 40 CFR § 194.25(a), concerned with predictions of  
37 the future states of society, requires that compliance assessments and performance  
38 assessments "shall assume that characteristics of the future remain what they are at the time  
39 the compliance application is prepared." Therefore, the effects of changes in future  
40 agricultural practices (such as **ranching, arable farming, and fish farming**) have been  
41 eliminated from performance assessment calculations on regulatory grounds.  
42

1 SCR.3.8.2 Social and Technological Developments

2  
3 *Demographic change and urban development in the near future and in the future have been*  
4 *eliminated from performance assessment calculations on regulatory grounds. Loss of records*  
5 *in the future is accounted for in performance assessment calculations.*  
6

7 Social and technological changes in the future could result in the development of new  
8 communities and new activities in the vicinity of the WIPP that could have an impact on the  
9 performance of the disposal system.

10  
11 Demography in the WIPP vicinity is discussed in Section 2.3.2.1. The community nearest to  
12 the WIPP site is the town of Loving, 18 miles (29 kilometers) west-southwest of the site  
13 center. There are no existing plans for urban developments in the vicinity of the WIPP in the  
14 near future. Furthermore, the criterion in 40 CFR § 194.25(a), concerned with predictions of  
15 the future states of society, requires that compliance assessments and performance  
16 assessments “shall assume that characteristics of the future remain what they are at the time  
17 the compliance application is prepared.” Therefore, **demographic change and urban**  
18 **development** in the vicinity of the WIPP and technological developments have been  
19 eliminated from performance assessment calculations on regulatory grounds.  
20

21 Human activities will be prevented from occurring within the controlled area in the near  
22 future. However, performance assessments must consider the potential effects of human  
23 activities that might take place within the controlled area at a time when institutional controls  
24 cannot be assumed to eliminate completely the possibility of human intrusion. Consistent  
25 with 40 CFR § 194.41(b), the DOE assumes no credit for active institutional controls for more  
26 than 100 years after disposal. Also, consistent with 40 CFR § 194.43(c), the DOE assumes  
27 that passive institutional controls do not eliminate the likelihood of future human intrusion  
28 entirely. Thus, the ineffectiveness of institutional controls in the future, represented in the  
29 FEP list in Table SCR-3 as **loss of records**, is accounted for in performance assessment  
30 calculations.  
31

32 **SCR.4 Modeling Scenario Forming FEPs**

33  
34 The preceding sections of Appendix SCR present the results of applying the methodology for  
35 screening FEPs, presented in Section 6.2 of the main text of this application. This section lists  
36 the FEPs that remain after screening and identifies  
37

- 38 • how each FEP is represented in the mathematical models used in the performance  
39 assessment calculations,
- 40
- 41 • which performance assessment code(s) and/or parameter(s) are used in the treatment  
42 of each FEP,
- 43
- 44 • the section(s) of the application that describe the treatment of the FEP in detail.

1 The FEPs that remain after screening are accounted for in performance assessment  
2 calculations either through explicit representation in the equations that form the mathematical  
3 models or implicitly through the specification of parameter values input to the performance  
4 assessment codes.<sup>6</sup> Tables SCR-5 and SCR-6 list the FEPs accounted for in calculations of  
5 disposal system performance under undisturbed and disturbed conditions respectively. In  
6 these tables, FEPs treated through explicit representation in the equations are incorporated as  
7 M, and those FEPs treated through the specification of parameters values are incorporated as  
8 P. FEPs incorporated as M generally require specification of parameter values as well. In  
9 some cases, a submodel is used to generate parameter values that are necessary for the  
10 solution of the basic governing equations of a computer code. FEPs incorporated by such  
11 submodels are generally denoted P. For example, the creep closure model provides porosity  
12 data to BRAGFLO and accounts for several FEPs incorporated as P.

13  
14 Tables SCR-5 and SCR-6 provide a link between the scenario-forming FEPs that are used to  
15 build the scenarios described in Section 6.3 and the conceptual and mathematical models  
16 described in Section 6.4. Codes and models mentioned are discussed in Section 6.4 and in  
17 appendices referenced from there.  
18  
19

---

1 <sup>6</sup> Performance assessment codes are those employed directly in the performance assessment calculations:  
2 BRAGFLO, NUTS, PANEL, SECOFL2D, SECOTP2D, CUTTINGS\_S, and CCDFGF.  
3

Table SCR-5. The Treatment of FEPs in Undisturbed Performance Scenarios

FEP Categorization	FEP Incorporation	FEP Treatment	Chapter Section
NATURAL FEPs			
Geological FEPs			
Stratigraphy			
Stratigraphy	P	Accounted for in the BRAGFLO model geometry	2.1.3 6.4.2
Structural FEPs			
Seismic activity			
Seismic activity	P	Accounted for in the DRZ permeability used by BRAGFLO	6.4.5.3
Geochemical FEPs			
Dissolution			
Shallow dissolution	P	Accounted for in the Culebra transmissivity fields	6.4.6.2
Subsurface hydrological FEPs			
Groundwater characteristics			
Saturated groundwater flow	M	Accounted for in BRAGFLO treatment of two-phase flow, and in SECOFL2D representation of flow in the Culebra	2.2.1 6.4.5 6.4.6
Unsaturated groundwater flow	M	Accounted for in BRAGFLO treatment of two-phase flow	2.2.1 6.4.6
Fracture flow	M	Accounted for in SECOTP2D treatment of flow in the Culebra	6.4.6.2
Effects of preferential pathways	P	Accounted for in the Culebra transmissivity fields	6.4.6.2
Subsurface geochemical FEPs			
Groundwater geochemistry			
Groundwater geochemistry	P	Accounted for in the actinide source term model, and in the actinide transport and retardation model used by SECOTP2D	2.2.1 6.4.6.2
Geomorphological FEPs			
Physiography			
Physiography	P	Accounted for in BRAGFLO model geometry	2.1.4 6.4.2
Surface hydrological FEPs			
Groundwater recharge and discharge			
Groundwater discharge	P	Accounted for in specification of boundary conditions to SECOFL2D	2.2.2 6.4.10.2
Groundwater recharge	P	Accounted for in specification of boundary conditions to SECOFL2D	2.2.2 6.4.10.2

Radiological FEPs			
Radioactive decay			
Radionuclide decay and ingrowth	M	Accounted for in NUTS, PANEL and SECOTP2D	6.4.12.4
Geological and mechanical FEPs			
Excavation-induced fracturing			
Disturbed rock zone	P	Accounted for in BRAGFLO parameter values and materials definition	6.4.5.3
Excavation-induced changes in stress	P	Accounted for in the creep closure model in BRAGFLO	6.4.3.1
Rock creep			
Salt creep	P	Accounted for in the creep closure model in BRAGFLO	6.4.3.1
Changes in the stress field	P	Accounted for in the creep closure model in BRAGFLO	6.4.3.1
Roof falls			
Roof falls	P	Accounted for in the permeability of the DRZ used by BRAGFLO	6.4.5.3
Subsidence			
Subsidence	P	Accounted for in CDF for permeability of DRZ used by BRAGFLO	6.4.5.3
Effects of fluid pressure changes			
Disruption due to gas effects	M	Accounted for in BRAGFLO fracture model for Salado interbeds	6.4.5.2
Pressurization	M	Accounted for in BRAGFLO fracture model for Salado interbeds	6.4.5.2
Effects of explosions			
Gas explosions	P	Accounted for in the permeability of the DRZ used by BRAGFLO	6.4.5.3
Mechanical effects on material properties			
Consolidation of waste	P	Accounted for in the creep closure model in BRAGFLO	6.4.3.1
Consolidation of seals	P	Accounted for in seal parameters used by BRAGFLO	6.4.4
Mechanical degradation of seals	P	Accounted for in seal parameters used by BRAGFLO	6.4.4
Underground boreholes	P	Accounted for in seal parameters used by BRAGFLO	6.4.5.3
