subject: Recommended Parameter Values for Modeling An(III) Solubility in WIPP Brines

1. Introduction

Parameter values for modeling speciation and solubility of actinides in the +III oxidation state (An(III)) from the recent literature (Morss and Williams, 1994; Könnecke et al., 1997; Fanghänel and Kim, 1998; Fanghänel et al., 1999) offer the opportunity to improve the An(III) speciation and solubility model implemented in the Fracture Matrix Transport (FMT) geochemical database. Newly available parameters include hydrolysis constants, constants for An(III) complexation with carbonate, chloride, and sulfate, Pitzer parameters describing the interaction of inorganic An(III) species with Na⁺, Cl⁻, and Ca²⁺, and solubility product constants (K_{sp}s) for An(OH)_{3(s)} and AnOHCO_{3(c)}.

This memo describes the implementation of the An(III) speciation and solubility model in the version of the FMT database used for the Performance Assessment Verification Test (PAVT)^{*}, and recommends a new implementation based on the recent literature. Recommended new values for complexation constants and Pitzer parameters were obtained from spectroscopic analysis of inorganic Cm(III) species in NaCl and CaCl₂ brines over a range of ionic strengths appropriate for determining the Pitzer ion interaction parameters necessary to simulate An(III) speciation in Waste Isolation Pilot Plant (WIPP) brines. Recommended new values for solubility product constants were obtained or verified by application of the recommended Pitzer models to independently collected Am solubility data.

2. An(III) Model in the PAVT Database

The An(III) speciation and solubility model in the PAVT version of the FMT geochemical database is that described by Novak (1995; 1996) with some modifications. Parameters are derived from Nd, Pu, Am, and Cm speciation and solubility data and applied to Am, the element that represents the +III oxidation state in the WIPP actinide solubility model (DOE, 1996). Because these four elements behave similarly when in the +III oxidation state (e.g. Rai et al., 1995; Felmy and Rai, 1999), complexation constants, solubility product constants, and Pitzer parameters for analogous species are assumed to be equal. The parameters used in the PAVT An(III) model are derived as follows:

^{*} The PAVT database is the most recent documented version of the database (Novak, 1997). It is stored in the CHEMDAT file FMT_970407.CHEMDAT in Sandia National Laboratories' Configuration Management System on the WIPP Alpha Cluster in the library WP\$NONPA_CMSROOT:[FMT].

Eccolone's evice in the National Interest

- 1. Am-chloride complexes are neglected. Am³⁺-Cl⁻ Pitzer ion interaction parameters are set equal to Nd³⁺-Cl⁻ interaction parameters calculated from the osmotic coefficient for NdCl₃ (Felmy et al., 1989; Pitzer and Mayorga, 1973).
- 2. First and second hydrolysis constants and related Pitzer parameters are derived from Cm speciation as a function of NaCl concentration (0.01-6.15 mol/kg) (Fanghänel et al., 1994). Fanghänel et al. (1994) successfully simulated $Am(OH)_{3(s)}$ solubility in 5 mol/L NaCl (Runde and Kim, 1995) using log K_{sp} = -28.2. In the PAVT database log K_{sp} = -26.2. Novak (1996) therefore adjusted the hydrolysis constants downward two orders of magnitude before entering them in the database.
- Novak (1996) estimated the third hydrolysis constant from the K_{sp} for Am(OH)_{3(s)} and experimentally determined Am(OH)_{3(s)} solubility in 5 mol/L NaCl at high pH (>11) (Runde and Kim, 1995). Novak (1996) assumed that the Pitzer parameters describing interaction of Am(OH)_{3(aq)} with Na⁺ and Cl⁻ are zero (i.e., the activity of Am(OH)_{3(aq)} is independent of ionic strength).
- 4. Carbonate complexation constants are derived from AmOHCO_{3(c)} solubility data in dilute (<0.1 mol/L) Na₂CO₃ solution (Felmy et al., 1990). Related Pitzer parameters used in the database were calculated by Rao et al. (1996), who used the Felmy et al. (1990) Am-carbonate complexation constants to simulate NaNd(CO₃)₂·6H₂O_(c) solubility in concentrated (0.1-2 mol/L) Na₂CO₃ solutions. Rao et al. (1996) verified the Pitzer parameters by successfully simulating the Felmy et al. (1990) AmOHCO_{3(c)} solubility data.
- 5. Am-sulfate complexes are neglected. Am³⁺-SO₄²⁻ Pitzer ion interaction parameters were calculated from Am solvent-extraction data in Na₂SO₄-H₂SO₄ solutions up to 0.5 mol/kg (Rai et al., 1995). The Pitzer parameters were verified by successfully simulating two independent data sets for Am-sulfate complexation in 1 mol/kg NaClO₄ and the solubility of NdPO_{4(s)} in the presence of SO₄²⁻ in dilute solution (Rai et al., 1995).
- Log K_{sp} for Am(OH)_{3(s)} is set equal to that for Pu(OH)_{3(s)} as determined from supersaturation and undersaturation experiments (-26.2, Felmy et al., 1989^{*}). Because these experiments were conducted at room temperature, the resulting precipitate can be assumed to be amorphous Pu(OH)₃ (e.g., Morss and Williams, 1994).
- Log K_{sp} for AmOHCO_{3(c)} (-22.5) was determined by monitoring the transformation of an amorphous Am-carbonate phase to a crystalline phase (essentially a supersaturation experiment) and by resuspending the crystalline phase in various solutions (undersaturation experiments) (Felmy et al., 1990).

The An(III) model also includes Pitzer ion interaction parameters describing the interaction of Am^{3+} with H₂PO₄⁻ (Rai et al., 1995) and Am^{3+} with ClO₄⁻ (Felmy et al., 1990), and solubility product constants for the solid phases NaAm(CO₃)₂·6H₂O (Rao et al., 1996) and AmPO_{4(s)} (Rai et al., 1992). In addition, the Pitzer parameters describing interaction of SO₄⁻²⁻ with ClO₄⁻ and Na⁺ were derived from Rai et al.'s (1995) study of Am-sulfate interaction. At this time I do not recommend any changes to these parameters except for setting the SO₄⁻²⁻ ClO₄⁻⁻ Na⁺ Pitzer parameters to zero for consistency with the recommended changes to the Am-sulfate model (see Section 3). Parameters describing Am interactions

- 2 -

with perchlorate and phosphate should possibly be re-evaluated if the FMT database is to be used to simulate solutions in which either perchlorate or phosphate is a dominant component. Neither is a component in WIPP geochemical models.

Tables 1-4 list the parameter values used in the PAVT An(III) model.

3. Shortcomings of the PAVT An(III) Model

The primary shortcomings of the PAVT An(III) model are related to (1) the way in which the Fanghänel et al. (1994) hydrolysis model was incorporated into the database, and (2) the limited range of ionic strength over which certain data were collected.

3.1. Hydrolysis model

The Fanghänel et al. (1994) parameters are appropriate for use in simulating WIPP brines, but their inclusion in the PAVT database was awkwardly implemented. Fanghänel et al. (1994) did not use the PAVT Am³⁺-Cl⁻ Pitzer parameters to develop the Pitzer parameters for Am-hydroxide species. Thus use of the Fanghänel et al. (1994) Pitzer parameters for Am-hydroxide species creates inconsistencies among Pitzer parameters in the database.

The combination of the Fanghänel et al. (1994) first and second hydrolysis constants with the Felmy et al. (1989) K_{sp} for Am(OH)_{3(s)} and Novak's (1996) estimated third hydrolysis constant imposes inconsistent constraints on Am(OH)_{3(s)} solubility. Novak (1996) adjusted the first and second hydrolysis constants for use in the PAVT database using the constraint that

 $\beta_{1n}^{0} K_{sp}^{0}$ (Fanghänel) = $\beta_{1n}^{0} K_{sp}^{0}$ (database),

where β_{1n}^0 is the appropriate hydrolysis constant at infinite dilution and the product $\beta_{1n}^0 K_{sp}^0$ is the equilibrium constant at infinite dilution for the dissolution reaction

 $Am(OH)_{3(s)} = Am(OH)_n^{3-n} + (3-n)OH^{-}$.

Use of the adjusted hydrolysis constants and the Felmy et al. (1989) log K_{sp} produces the same amount of AmOH²⁺ and Am(OH)₂⁺ in equilibrium with Am(OH)_{3(s)} as would using the complete Fanghänel et al. (1994) model. In effect, if AmOH²⁺ or Am(OH)₂⁺ is the dominant Am species in solution (as predicted for WIPP brines; Novak et al., 1997), the log K_{sp} for Am(OH)_{3(s)} is -28.2. If Am(OH)_{3(aq)}, Am³⁺, or other species is the dominant Am species in solution, the log K_{sp} for Am(OH)_{3(s)} is -26.2.

3.2. Ionic strength

Pitzer parameters for the PAVT Am-carbonate and Am-sulfate models were derived and/or verified using data collected in solutions containing $\leq 4 \text{ mol/L Na}^+$ and $\leq 1 \text{ mol/kg Na}^+$, respectively. Neither set of Pitzer parameters was tested on a solution containing Cl⁻. The PAVT database includes parameters describing the ternary interaction of $\text{Am}(\text{CO}_3)_3^{3^-}$, Cl⁻, and Na⁺, but the origin of these parameters is unknown. Models derived from data collected in solutions more similar to WIPP brines (i.e. solutions containing more Na⁺ and Cl⁻) would be preferable.

g = 1 - 1 + 4 + 4

4. Recommended An(III) Model

The recommended parameter values discussed in this section are derived from some of the same data that resulted in the PAVT version of the An(III) model plus more recently collected experimental data. The recommended model includes revisions to the third hydrolysis constant and Pitzer parameters for hydrolysis species, revisions to carbonate complexation constants and corresponding Pitzer parameters, addition of chloride and sulfate complexes, and revisions to $Am(OH)_{3(s)}$ and $AmOHCO_{3(c)}$ solubility product constants. The recommended model closely follows that proposed by Fanghänel and Kim (1998). Specifically, parameters are derived as follows:

- 1. Am-chloride complexes (AmCl₂⁺ and AmCl²⁺) are included on the basis of spectroscopic evidence for the existence of CmCl₂⁺ and CmCl²⁺ in 2-6 mol/kg CaCl₂ (4-12 mol/kg Cl⁻) solution (Fanghänel et al., 1995). Complexation constants for these chloride complexes, Pitzer parameters describing interaction of Am³⁺, AmCl₂⁺, and AmCl²⁺ with Cl⁻ and Ca²⁺ are set equal to those calculated by Könnecke et al. (1997) from the Cm speciation data of Fanghänel et al. (1995).
- 2. First and second hydrolysis constants remain equal to those calculated by Fanghänel et al. (1994) from Cm speciation data. Related Pitzer parameters are set equal to those calculated by Könnecke et al. (1997) from the Fanghänel et al. (1994) data set. The Könnecke et al. (1997) recalculation of these Pitzer parameters accounts for the presence of Cm-chloride complexes and includes a term describing the interaction of Cm³⁺ with Na⁺ (θ).Könnecke et al.'s (1997) successful use of their model to simulate Cm speciation in NaCl solution validates the absence of Pitzer parameters describing interaction between Am-chloride complexes and Na⁺.
- 3. The third hydrolysis constant is set equal to that recommended by the Nuclear Energy Agency (Silva et al., 1995). Könnecke et al. (1997) used this value and the K_{sp} for Am(OH)_{3(s)} recommended by Morss and Williams (1994) to successfully simulate the Am(OH)_{3(s)} solubility data of Runde and Kim (1995). Könnecke et al.'s (1997) model included Pitzer parameters describing the interaction of Am(OH)_{3(aq)} with Na⁺ and Cl⁻.
- 4. An additional Am-carbonate species (Am(CO₃)4⁵⁻) is included on the basis of spectroscopic evidence for the existence of Cm(CO₃)4⁵⁻ (Fanghänel et al., 1999). Carbonate complexation constants and related Pitzer parameters are derived from Cm-carbonate speciation data collected over a range of NaCl concentrations from 0-6 mol/kg (Fanghänel et al., 1999). Fanghänel et al. (1999) neglected the formation of Am-chloride complexes in their model, a valid decision at chloride concentrations <6 mol/kg (Fanghänel et al., 1995). They verified their model by successfully simulating the solubility of AmOHCO_{3(c)} (including the Felmy et al. (1990) data set) and NaAm(CO₃)_{2(s)}.
- Am-sulfate complexes are included on the basis of spectroscopic evidence for the existence of CmSO₄⁺ and Cm(SO₄)₂ (Paviet et al., 1996). Related Pitzer parameters are derived from Cm-sulfate speciation data collected over a range of NaCl concentrations from 0-6 mol/kg (Fanghänel and Kim, 1998).
- 6. The log K_{sp} for Am(OH)_{3(s)} (-27.5) is equal to that recommended by Morss and Williams (1994) on the basis of a compilation of values from the literature. This is the value Könnecke et al. (1997) successfully used to simulate Runde and Kim's (1995) Am(OH)_{3(s)} solubility data.

7. The log K_{sp} for AmOHCO_{3(c)} (-22.7) is equal to that calculated by Fanghänel et al. (1999) on the basis of Felmy et al.'s (1990) AmOHCO_{3(s)} solubility data.

Tables 1-4 list the recommended parameter values and compare them to the values used in the PAVT version of the database.

5. Benefits of the Recommended Model

The recommended model is superior to the PAVT model in that:

- 1. The Am-hydrolysis model is self-consistent, consistent with the Am-chloride model, and consistent with the choice of $Am(OH)_{3(s)} K_{sp}$. The recommended value for log K_{sp} of $Am(OH)_{3(s)}$ (-27.5) in combination with the recommended Pitzer model predicts essentially the same Am solubility (in 5 M NaCl) predicted by the PAVT model in the pcH (-log [H⁺]) region relevant to the WIPP (pcH = 9-10). At higher and lower pH, the recommended model provides a better fit to the Am solubility data of Runde and Kim (1995) (Figure 1).
- The Am-carbonate and Am-sulfate models were derived from data collected over a range of NaCl concentration from 0-6 mol/kg (Fanghänel and Kim, 1998; Fanghänel et al., 1999). Therefore the Pitzer ion interaction parameters associated with these models can be more confidently applied to WIPP brines than the parameters in the PAVT model, which were derived from data collected at Na⁺ concentrations ≤4 mol/L and in the absence of chloride.
- 3. The inclusion of Am-chloride species extends the useful range of the An(III) model to chloride concentrations up to 12 mol/kg (the maximum amount of Cl⁻ present in the experiments from which the Am-chloride model is derived). Extension of the model to higher chloride concentrations will result in a slight improvement in simulations of WIPP brines, which (as represented in the PAVT) have chloride concentrations as high as 6.7 mol/kg (Novak et al., 1997). The inclusion of Pitzer parameters describing the interaction of Am-chloride species with Ca²⁺ will also slightly improve simulations of WIPP brines, and will allow use of the An(III) model to simulate high ionic strength brines dominated by CaCl₂. Application of the Ca²⁺ Pitzer parameters to Mg²⁺ interactions with Am-chloride species may also improve the model for use in modeling high Mg brines, including WIPP brines. Whether such application is appropriate remains to be determined.
