1.0 INTRODUCTION

This report presents data collected between October 1997 and October 1998 as part of the ongoing Exhaust Shaft Hydraulic Assessment Program at the Waste Isolation Pilot Plant (WIPP) located in Southeastern New Mexico (Figure 1.1). This program was implemented in an effort to monitor and characterize source(s) of fluid leaking into the upper 85 feet of the Exhaust Shaft at the WIPP for the past several years. Though leakage into the shaft is small in volume, an assessment program was implemented to characterize the near-surface hydrology in an effort to understand the origin of the leaking fluid. This program has used a phased approach involving drilling, core descriptions, well completions, water-level monitoring, hydrologic testing, and water-quality sampling and analysis. This study is confined to the surface-facility area at WIPP.

In Phase One, three wells were drilled in 1996 near the Exhaust Shaft. Drilling and testing indicated that groundwater was not confined to the immediate Exhaust Shaft area and that the water occurred in a perched water-bearing horizon in the Santa Rosa Formation at or near the contact of the Santa Rosa with the underlying Dewey Lake Formation. In addition, hydraulic tests indicated that the wells yield no more than 1.0 gallons per minute (gpm) for extended periods of pumping. In Phase Two, twelve piezometers were drilled, expanding the area of investigation for water-quality sampling and testing. Drilling and testing indicated that the areal extent of the water in the Santa Rosa extends beyond the present 80-acre investigation, though bounded to the southeast by a dry hole, piezometer PZ-8 (Figure 1.2). Water-level data indicates that there is a potentiometric high located near PZ-7 in the northwestern portion of the site. Based on the potientiometric surface data, water appears to flow from west to east in the northern portion of the site, and from northwest to southeast and south in the southern portion of the site (DOE, Dec. 1997).

Water-quality sampling data collected from the wells and piezometers was categorized into three groups based on total dissolved solids (TDS). The first group, consists of high TDS (greater than 70,000 mg/L), and represents water found in the central and northeastern section of the site located near the north salt pile and a previously existing drilling pit used during construction of the Salt Shaft. The second group, consisting of intermediate TDS (20,000 – 70,000 mg/L), represents an area located in the northwest WIPP site area near the north salt pile retention pond, a suspected recharge area, and central portion of the site. The third group, consisting of low TDS (less than 20,000 mg/L) is located in the southern portion of the site near several rainfall runoff retention ponds.

This assessment updates previous reports and is based on data collected from October 1997 through October 1998 from wells and piezometers completed in the perched water-bearing horizon located in the Santa Rosa Formation at the WIPP (Figure 1.3). In addition, other data such as rainfall precipitation and Exhaust Shaft flow and pressure data are examined to identify possible trends affecting the hydrology within the Santa Rosa Formation.

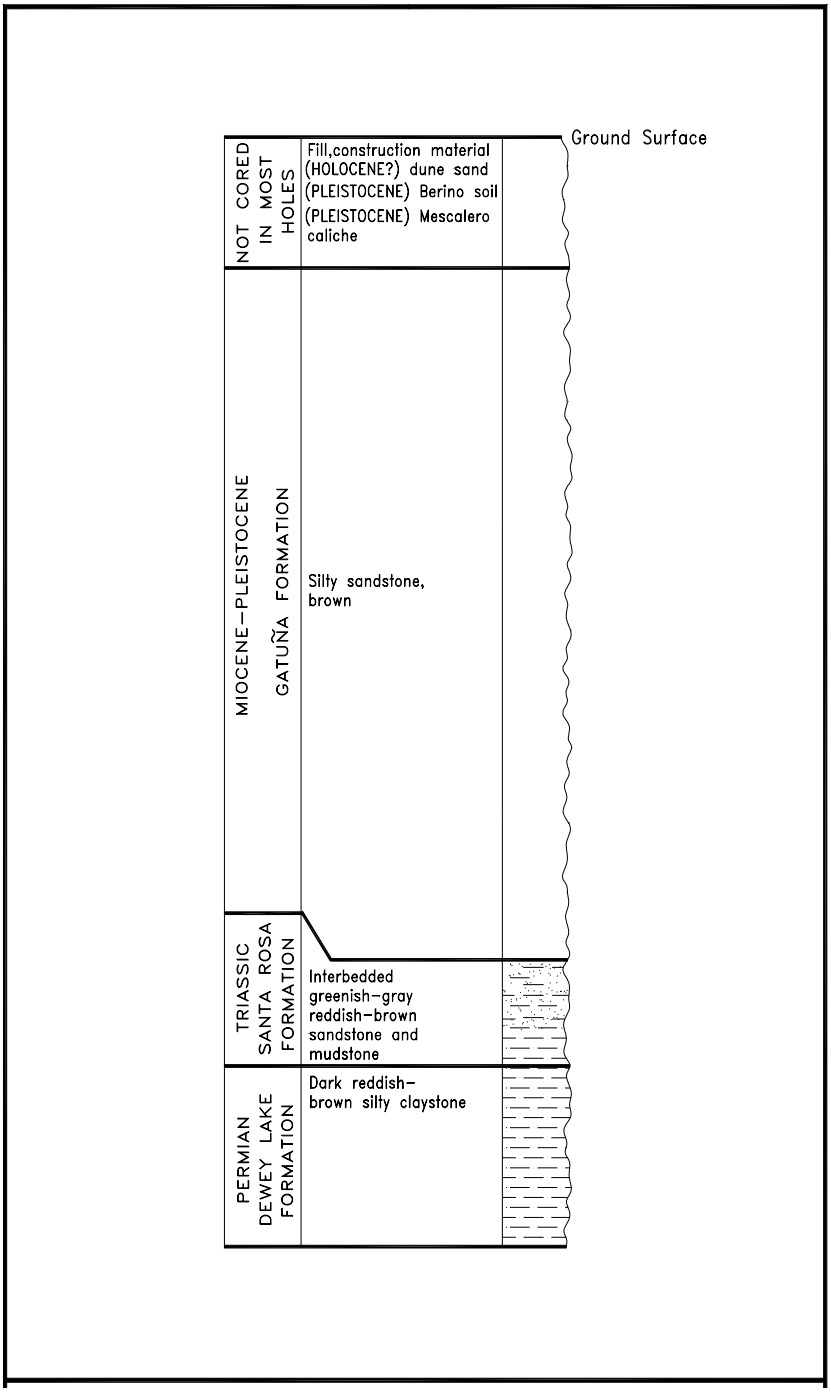

Figure 1.3 - Units Commonly Encountered During Shallow Drilling at WIPP

1.1 Background

Fluid migrating into the Exhaust Shaft at the WIPP site was first documented during a May 1995 shaft video inspection. Fluid was observed flowing from cracks in the Exhaust Shaft concrete liner at depths of 55 to 85 feet below ground surface (bgs).

Surface geophysical investigations noted possible fluid-conductive zones in the shallow soil and bedrock in the vicinity of the Exhaust Shaft and as the results were reported in Exhaust Shaft: Hydraulic Assessment Data Report (DOE, Jan. 1997). Four boreholes were drilled in September and October 1996 to depths of up to 100 feet bgs to evaluate near surface formations as potential sources of the fluid seeping into the Exhaust Shaft. Four boreholes (C-2505, C-2506, C-2507, and ES-001) penetrated water-bearing horizons between 48 and 63 feet bgs located in the sandstone of the lower Santa Rosa and mudstone of the upper Dewey Lake Formations. Three boreholes (C-2505, C-2506, and C-2507) were drilled and selectively cored to determine the stratigraphic horizons producing fluid and were then completed as monitoring wells (Figure 1.2). The Dewey Lake Formation appears to act as an impermeable layer, though a thin weathered zone (~1-2 ft thick) at the top of the Dewey Lake may also be saturated.

During drilling of C-2505, C-2506, and C-2507, the base of the Santa Rosa Formation was first estimated to be at depths of 48.8, 48.2, and 39.5 ft bgs, respectively (DOE, Jan. 1997). However, based on the core samples recovered from C-2505 and subsequent drilling of the PZ holes at the site (DOE, Dec. 1997), the top of the Santa Rosa is probably 39.6-ft bgs in drill hole C-2505 (personal communication Powers, 1999, see Appendix 1). This depth is more consistent with observations in the Exhaust Shaft (Holt and Powers, 1986) as well. For C-2506 and C-2507, the top of the Santa Rosa appears to be above the initial coring depths of each drill hole. Please refer to Figures 1.4, 1.5, and 1.6 for revisions to the well completion diagrams for C-2505, C-2506 and C-2507 relative to earlier reports.

As a result of these revisions, several figures in Powers (DOE, Dec. 1997) were modified. Figures 11 and 12, which show the elevation of the top of the Santa Rosa in detail, indicate a smaller area lower than 3365-ft amsl and the contour for 3370-ft amsl will be south of the exhaust-shaft area. Figures 12 and 13, which show the thickness of the Gatuña Formation will indicate corresponding changes around the shaft area, with thickness reduced by about 9 ft. The general shape of the contours is not changed, nor are any conclusions about the formation of these units changed. For convenience basic stratigraphic data for each drill hole in the PZ boreholes, C-wells, and the Exhaust Shaft are presented in Table 1.1.

*ND = not determined. Depths are approximate (about ±1 ft). Some contacts to nearest 0.5 ft due to marked contrast. Where the Gatuña-Santa Rosa contact is difficult to identify; the Gatuña is incorporated with Santa Rosa.

Hydraulic tests were conducted on wells C-2505, C-2506, and C-2507 in October 1996 to characterize the water-bearing horizons. Test data provided hydraulic conductivity values ranging from 5.5 x E-5 to 1.6 E-6 m/sec, with storativity values ranging from 1.1 x E-2 to 9.4 x E-3. Water-level data were used to calculate a hydraulic gradient of 0.0245 ft/ft in a south/southeasterly direction. Test data indicated that the wells nearest the Exhaust Shaft were capable of sustained water production rates of about to 0.6 gallons per minute (gpm) (DOE, Jan. 1997).

Water samples were collected from wells C-2505, C-2506, and C-2507 a few days after drilling. The water-quality data from these wells indicated that total dissolved solids (TDS) were greatest near the Exhaust Shaft ranging from 11,500 mg/L in C-2506, to 8,500 mg/L in C-2505, and to 4,000 mg/L in C-2507 located 200 feet to the south of the shaft.

Further hydrologic testing was conducted in February and March 1997. Testing consisted of a 72-hour pumping test in C-2506 and a 24-hour pumping test in C-2505, C-2506, and C-2505 were pumped at rates ranging from 0.5 to 1.0 gpm. In addition, water-quality samples were collected from each well at the completion of testing. Water-level data collected between October 1996 and March 1997 revealed that during that

time water levels had risen from 1.6 to 2.6 feet in wells C-2505, C-2506 and C-2507. Fresh-water-head values calculated from water-level and water-quality data indicated a 6-foot difference between well C-2506 near the Exhaust Shaft and C-2507 to the south. Based on water-level measurements collected on March 24, 1997, the hydraulic gradient increased to 0.032 ft/ft in a south/southeasterly direction.

Water-quality samples were collected upon the completion of the 72-hour pumping test in well C-2506 and upon completion of the 24-hour pumping test in C-2505. In both wells the total dissolved solids concentrations were less than observed in October 1996. In C-2506, the TDS decreased from about 11,500 to 6,000 mg/L, while in C-2505 the TDS decreased from about 8,500 to 4,500 mg/L.

In June and July 1997 twelve 6-5/8-inch boreholes were hollow-stem augered/cored and/or air-rotary drilled to depths of up to 82 feet bgs through the Santa Rosa Formation into the Dewey Lake Formation (Figure 1.2). Each borehole was completed with a 2-inch piezometer, packed with sand above the screened intervals, sealed with bentonite, and grouted to ground surface. The locations and elevations of each piezometer (PZ-1 through PZ-12) were surveyed immediately upon completion of each installation. Elevation data were then used with water-level measurement data to determine the location of succeeding piezometers which were used to define the hydraulic gradient, and to determine the areal and vertical extent of fluid within the Santa Rosa Formation.

Of the twelve piezometers and three wells installed at WIPP between September 1996 and August 1997, only PZ-8 was dry. Water was present in all other monitoring wells, indicating that the investigative area bounded by PZ-11 to the north and west, PZ-12 to the south, and PZ-9 to the east appears to contain a constant zone of saturation above the perching horizon (Figure 1-2).

Water-level measurements indicated that fluid levels in wells rose as much as 2.0 feet or more between October 1996 and September 1997. Water-level changes exhibit characteristics commonly associated with local recharge, such as an apparent response to local precipitation events. These responses suggest that area(s) of local recharge probably exist. Potential sources of recharge include features such as local precipitation captured by the north salt disposal mound, the retention ponds located along the south border of the site, the salt evaporation pond west of the north disposal mound, or releases/leaks possibly from on-site water, drainage or sewage systems.

Equipotential surface maps of the water levels in the Santa Rosa suggest that a potientiometric high exists in the northwest corner of the 80-acre WIPP site investigative area at the salt evaporation pond west of the north salt disposal mound. Flow lines indicated that fluid flow in the Santa Rosa Formation is from the northwest to the east, and south and southeast across the site (DOE, Dec. 1997).

After installation, each piezometer was pumped to determine the hydraulic parameters of the perched-water zone. In addition, fluid samples were collected to characterize the areal water quality at the WIPP site. Hydraulic conductivity values for the tested

piezometers ranged from 2.1 x E-5 to 2.6 x E-8 m/s. Table 1.2 lists the hydraulic conductivity values from tests performed on wells C-2505, C-2506, C-2507, and piezometers PZ-1 through PZ-12. The higher conductivity values are typically located in the western and southern portion of the site, while the lower conductivity values are found in the northern and eastern portion of the site.

Table 1.2 Hydraulic Conductivity Estimates

Well/Piezometer	Hydraulic Conductivity (m/s)
C-2505	7.8E-6
C-2506	2.0E-5
C-2507	6.0E-6
PZ-1	5.7E-8
PZ-2	2.6E-8
PZ-3	No Testing Performed
PZ-4	2.4E-6
PZ-5	1.4-E-7
PZ-6	3.8E-6
PZ-7	1.7E-6
PZ-8	Dry hole
PZ-9	No Testing Performed
PZ-10	5.2E-6
PZ-11	3.3E-6
PZ-12	2.1E-5

Water-quality samples were collected from the wells and piezometers in July 1997. Analysis of samples indicated total dissolved solids (TDS) values ranging from 3,700 to 155,000 (DOE, Dec. 1997). Data indicated an area of high TDS in the vicinity of PZ-3 and low TDS in the southern portion of the site. Plots of Cl/Br ratio versus location and potassium concentration versus location indicated three types of groundwater in the shallow aquifer beneath the WIPP site (DOE, Dec. 1997). One type is located around the Exhaust Shaft: a second type in the central and north central part of the site; and a third type in the west and southwest part of the site. Data also indicate that potassium-rich groundwater occurs in the central and the north-central WIPP site area.

1.2 Objectives

A summary report, describing the investigations of Exhaust Shaft inflow was published in December 1997 and entitled Exhaust Shaft: Phase 2 Hydraulic Assessment Data Report: Involving Drilling, Installation, Water-Quality Sampling, and Testing of

Piezometers 1-12 (DOE, Dec. 1997). Since that time water-level measurements and water-quality samples have been collected and periodically analyzed to establish and identify trends in order to improve understanding of the hydrologic conditions within the Santa Rosa Formation. This report has three objectives:

- To present and assess the hydrologic, chemical, and meteorological data collected between October 1997 and October 1998;
- To develop a conceptual model that describes the perched unconfined water-bearing horizon in the Santa Rosa; and
- Based on that model, identify those areas where ambiguities exist in the data or where there is insufficient data to define the hydrologic system.

1.3 Scope of Work

Water-level measurements and water-quality samples were collected periodically between October 1997 and October 1998 from fifteen well and piezometer locations across the WIPP site to characterize the extent and quality of water present in the Santa Rosa Formation. In addition, WIPP site precipitation data and Exhaust Shaft pressure and fluid-flow data were collected to identify trends concerning fluid-flow migration into the shaft.

2.0 CONSTRUCTION

Five boreholes were drilled in September and October 1996, three of which were completed as wells for the monitoring of water levels and water quality sampling. During the second phase, twelve boreholes were drilled and completed as piezometers providing additional information concerning the WIPP site hydrogeology and water chemistry.

2.1 Wells C-2505, C-2506, and C-2507

Boreholes C-2505, C-2506, and C-2507 were drilled in September and October 1996 (DOE, Jan. 1997). The boreholes were drilled to depths of up to 97 feet below ground surface (bgs) using either hollow-stem auger or air-rotary methods. The wells were screened and gravel packed through the Santa Rosa Formation and sealed with several feet of bentonite clay and grouted to the surface. Figure 2.1 is a diagram of a typical well completion for wells C-2505, C-2506, and C-2507.

2.2 Piezometers PZ-1 through PZ-12

Twelve 6-5/8-inch diameter boreholes were hollow-stem augered/cored and or air-rotary drilled to depths of up to 82 feet bgs through the Santa Rosa Formation into the Dewey Lake Formation between June 23 and July 10, 1997 (DOE, Dec. 1997). As the boreholes were completed, 2-inch I.D. piezometers were installed, packed with sand above the screened intervals, sealed with bentonite, and grouted to ground surface.

Figure 2.2 is a typical well completion diagram for the twelve piezometers installed at WIPP.

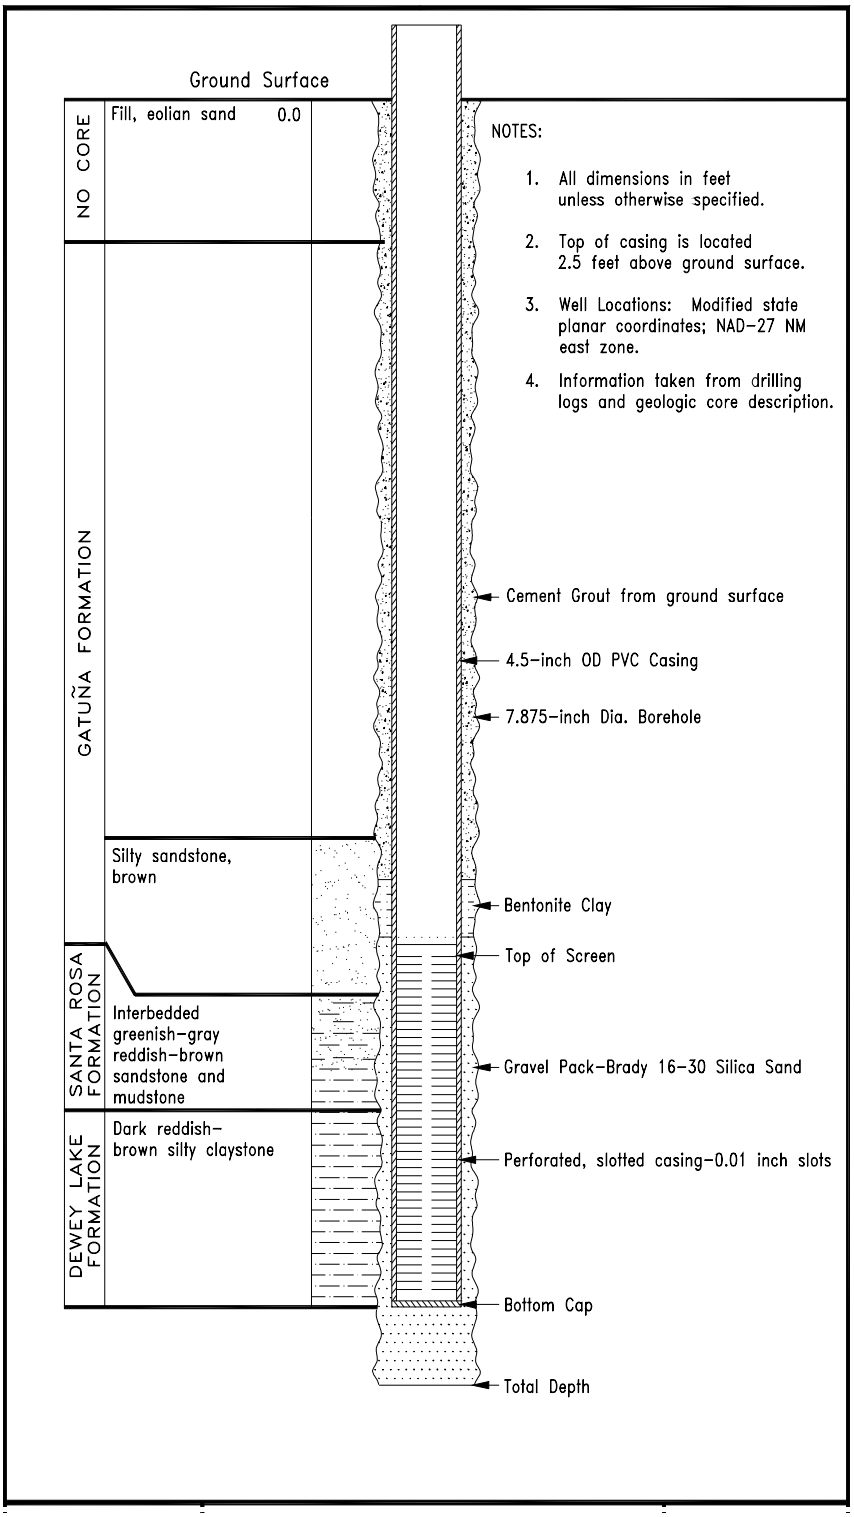

Figure 2.1 - Typical Well Completion Diagram

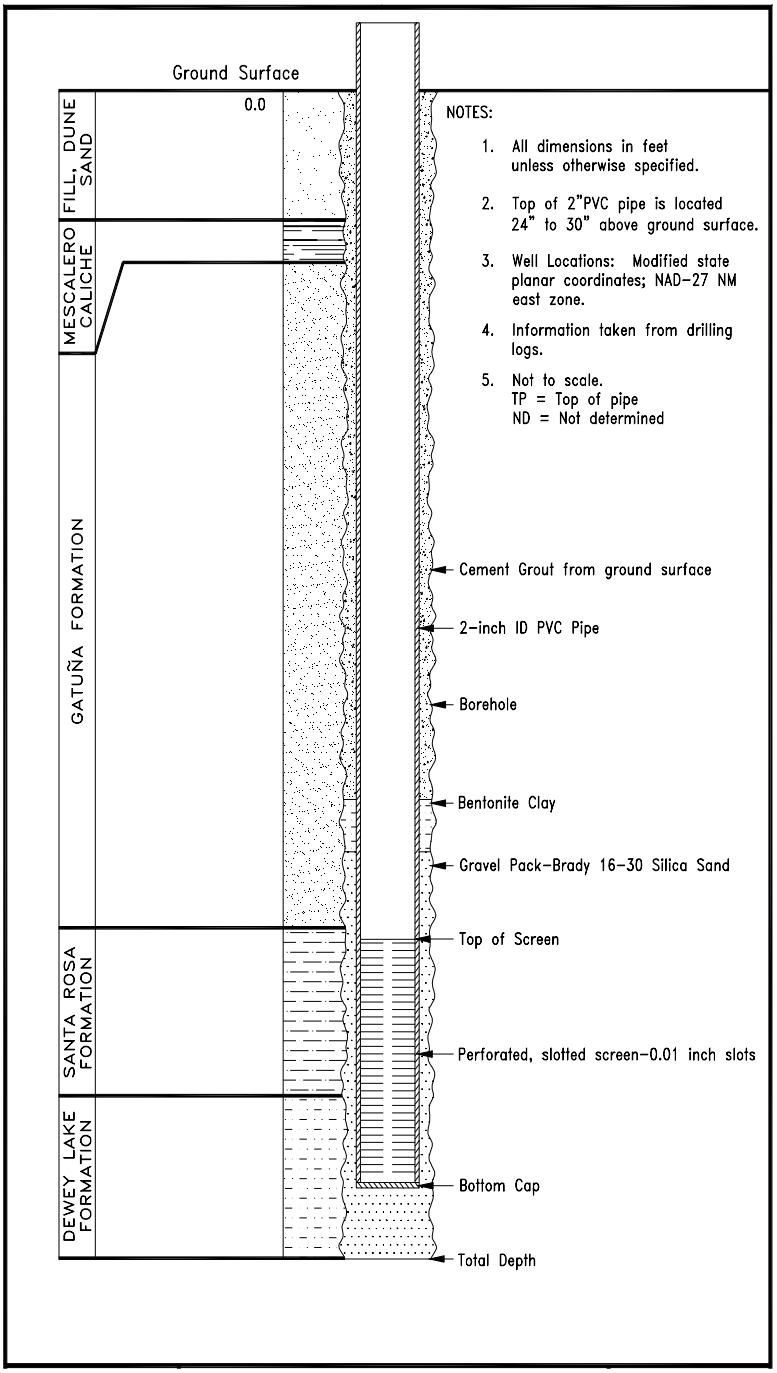

Figure 2.2 - Typical Piezometer Completion Diagram

3.0 GEOLOGY

Cores and cuttings were collected from boreholes completed during Phase I and Phase II activities of the Exhaust Shaft Hydraulic Assessment Program. Descriptions and interpretation of cores, cuttings and geological data were performed by Dr. Dennis Powers. Powers identifies seven geologic units encountered during drilling and coring of the fifteen boreholes covered under this assessment program. From the surface down, these are:

- Fill - local units disturbed by construction or material brought in for construction,
- Holocene (?) dune sand,
- Pleistocene Berino soil
- Pleistocene Mescalero caliche
- Miocene - Pleistocene Gatuña Formation
- Triassic Santa Rosa Formation
- Permian Dewey Lake Formation

Fill, Construction Materials. Around the facilities, significant areas have been modified by construction activities. Much of the dune sand has been leveled in place, though some of the upper part has been removed as "soil" for later rehabilitation following decommissioning of the WIPP facility. Gravel from nearby caliche pits has been imported to stabilize the roadway and construction surfaces, and one hole, PZ-1, was drilled through asphalt surfacing. Another hole, PZ-7, was located on top of a small berm, constructed of dune sand with caliche surfacing around an evaporation pond.

Holocene (?) Sand Dunes. The most recent widespread sedimentary deposit at the WIPP site is a thin blanket of windblown sand. The sand, known as the Mescalero sand, occurs as relatively inactive dunes, except in areas where local wind-related blowouts occur. Nearly eight feet of unconsolidated sand occurs at the Exhaust Shaft. This sand is reddish-brown, silty, and poorly sorted.

Berino Soil. The Berino soil is a dark reddish brown siltstone to argillaceous sandstone that is partially lithified, mainly by accumulations of clay minerals. It is a fossil soil.

Mescalero Caliche. The Mescalero caliche in the area of the WIPP is an informal stratigraphic unit designated by Bachman (1976) for the pedogenic carbonate deposits across the Mescalero plains. The unit is locally variable in thickness and disrupted by erosion/solution prior to the formation of the Berino soil. The upper one foot of the caliche is typically hard, and the hardness and overall degree of induration decreases with depth. It also becomes nodular with depth and the size of the nodules increase with depth. Locally, siltstones and sandstones are engulfed by the caliche. Chert and sandstone pebbles are engulfed higher in the section.

Miocene-Pleistocene Gatuña Formation. The Gatuña is a poorly sorted, fine to very fine grained, friable, calcareous sandstone. The lower 1.5 feet of the Gatuña contain angular debris from the underlying Santa Rosa Formation. The thickness of the unit can vary considerably over short distances. Several caliche quarries east of the WIPP

withdrawal area expose well-lithified Santa Rosa under caliche. The Gatuña Formation is relatively thin across most of the site facility area at the WIPP. The Gatuña thickens considerably to the west, especially along Nash Draw and nearer the present day Pecos River (Powers and Holt, 1993, 1995). It was deposited in localized fluvial channels caused by erosion.

Triassic Santa Rosa Formation. In the WIPP site area, the Santa Rosa Formation occurs as an erosional wedge that pinches out west of the WIPP site. It thickens rapidly to the east as a consequence of both eastward dip and eastward rise in the surface elevation. The Santa Rosa consists of calcareous reddish-brown siltstone and fine-grained sandstone and contains pebbles of chert.

Dewey Lake Formation. The Dewey Lake is characterized by its reddish-orange to reddish-brown color and varying sedimentary structures. In the Exhaust Shaft, the Dewey Lake consists almost entirely of mudstone, claystone, siltstone, and interbeded fine-grained sandstone.

4.0 HYDROLOGY

Section 4.0 examines hydrologic data collected over the past three years at the WIPP site as a part of the hydraulic characterization of water inflow to the Exhaust Shaft. Data includes water-level data, water-quality sampling data, Exhaust Shaft instrument pressure data, fluid data for water collected at the bottom of the Exhaust Shaft, and precipitation data collected at the WIPP site weather station.

4.1 Water-Level Data

Water-level measurements have been collected in wells C-2505, C-2506, and C-2507 since October 1996 and in PZ-1 through PZ-12 since July 1997. Water-level measurement data are used to determine the pressure head at a point, the regional hydraulic gradient, the direction of groundwater flow, and possible areas of recharge and discharge. Figure 4.1 is a linear plot of water-level measurements collected from the fifteen Santa Rosa monitoring wells and piezometers through October 1998. The plot shows that typically fluid levels rose in all wells until early 1998 when the pattern changed. In many wells fluid levels then became static or began to drop slightly. The highest pressure-head values were found in wells PZ-7 and PZ-11 located in the northwestern portion of the WIPP site. The lowest head values are found at wells PZ-12 to the south, PZ-9 to the northeast, and C-2507 the southeast portion of the WIPP site. In addition, PZ-8 is a dry hole indicating that there is a saturation front located somewhere west of PZ-8.

Figure 4.2 is an equipotential water-level surface map of the Santa Rosa Formation at WIPP as of October 1998. Flow lines indicate that water moves from the west to the east in the northern portion of the site, while fluid flows from the north to the south and southeast in the western and central portion of the site. The hydraulic gradient between PZ-7 (potentiometric high) and PZ-12 (potentiometric low) is about 0.014 ft/ft.

Based on Figures 4.1 and 4.2, wells PZ-7 and PZ-11, located in the vicinity of the north salt pile retention pond appear to be in a recharge area. PZ-7 has a total head of 3374.92 feet (amsl), at least 3.5 feet higher than the fluid level in any of the other wells and piezometers monitoring the Santa Rosa at WIPP. Areas of low total hydraulic head are located primarily to the south and east. There is likely a saturation front, which extends radially outward from the WIPP site, as evidenced by an absence of water in PZ-8. Though there has been some change in the total head in each of the wells and piezometers over the past two years, there has been no significant change in the overall hydrology (i.e., gradient, flow direction, and areas of recharge and discharge).

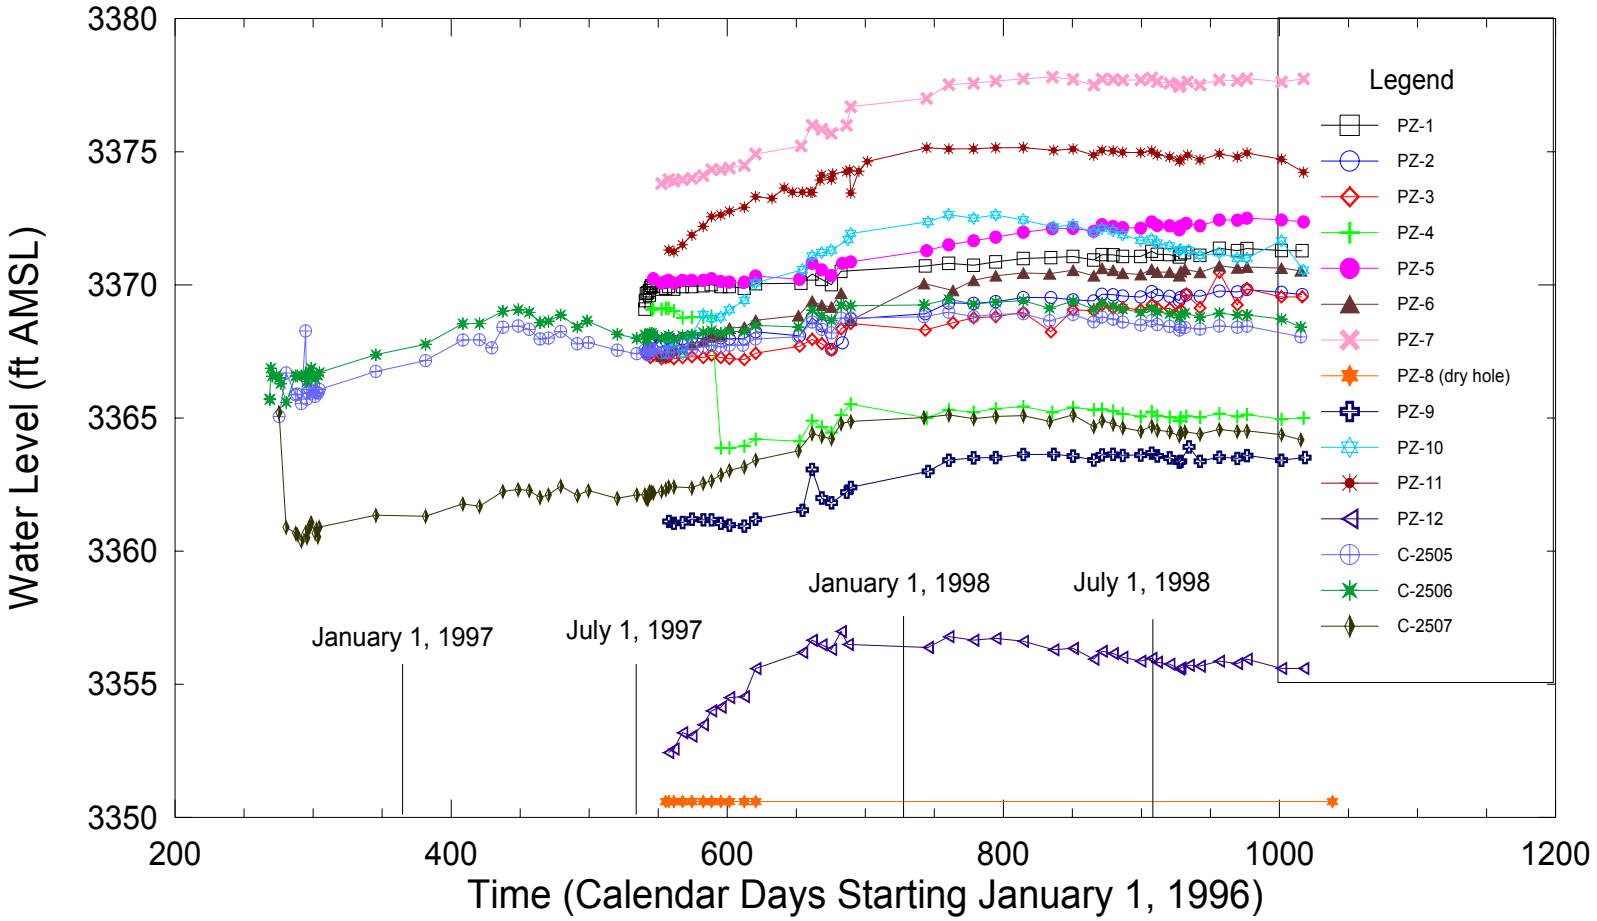

Figure 4.1 - Linear Plot of Water Levels for Wells and Piezometers Located in the Santa Rosa Formation as of October 1998

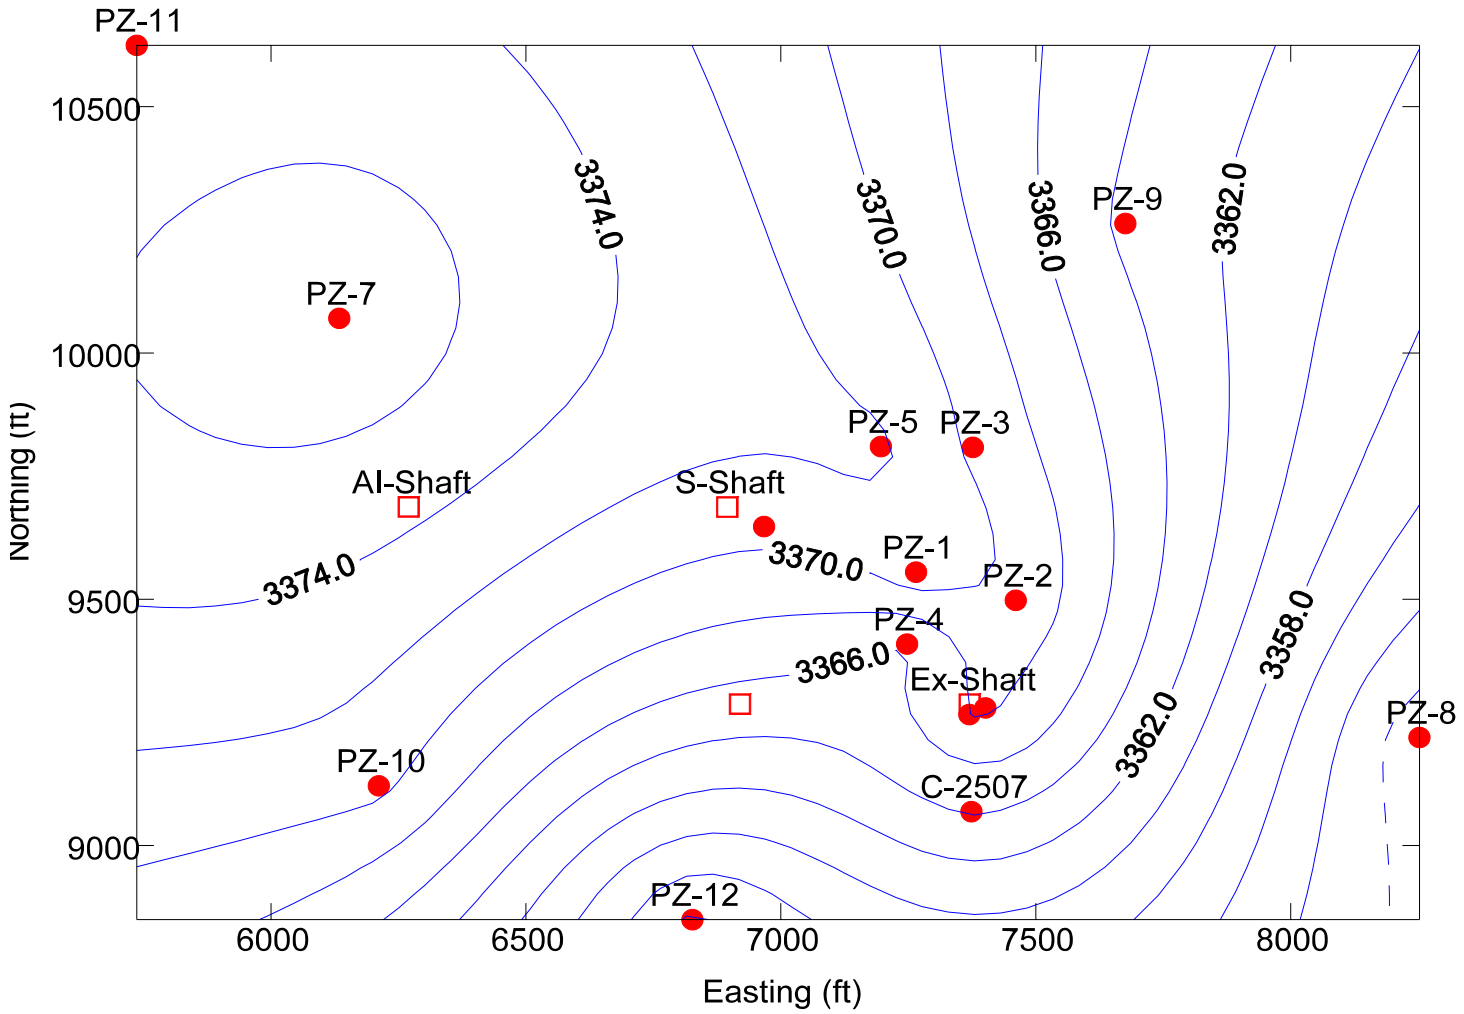

Figure 4.2 - Equipotential Water-Level Surface Map for the Santa Rose Formation as of October 1998

4.2 Water Quality Data

Periodic water-quality samples have been collected from the fifteen well and piezometer locations monitoring the Santa Rosa Sandstone since July 1997. Samples were collected on a quarterly basis in order to establish trends, and to characterize and identify the origin(s) of the water (Appendix 2). Figure 4.3 is a plot of Total Dissolved Solids (TDS) versus time for samples collected from the fifteen wells and piezometers. This plot shows that, for the most part, TDS values have been relatively stable for the past 18 months. Based on the plots of TDS data, TDS can be grouped into three categories: high TDS (70,000 to 170,000 mg/L), intermediate TDS (20,000-70,000 mg/L), and low TDS (0-20,000 mg/L).

In Figure 4.4 TDS is plotted with equipotential freshwater head values for the Santa Rosa Formation. The plot clearly identifies a high TDS region located in the northeastern portion of the site that includes PZ-1, PZ-3, PZ-5, and PZ-9. The intermediate TDS region includes the northwestern and central portion of the site including P-4, PZ-6, PZ-7, and PZ-11. The low TDS region includes PZ-2, PZ-10, PZ-12, C-2505, C-2506, and C-2507.

Given their terrigenous sedimentary composition, the Gatuña and Santa Rosa Formations have insufficient halite to support high levels of total dissolved solids. Therefore, the highly saline water does not represent original groundwater. The high total dissolved solids concentration in the Santa Rosa may be linked to localized surface recharge associated with site evaporation and retention ponds. Pumping test data indicates that the Santa Rosa is an unconfined aquifer (DOE, Dec. 1997) providing appropriate conditions for the migration of fluid from the surface. Table 4.1 lists the stratigraphic depths for the Gatuña, Santa Rosa, and the Dewey Lake Formations and the water level for each well. Given that the water is unconfined, localized saline water recharge is the most likely source of the high TDS fluid.

The first potential high TDS source is the North Salt Storage Area which contains material mined from the WIPP repository horizon in the predominantly halite Salado Formation. In addition to being highly soluble disaggregated salt, the moat along the south side of the North Salt Storage Area was also the area where saline-construction and sump-collection water removed from the WIPP repository horizon was discharged for several years. The North Salt Storage Area probably still serves as a major source of recharge to the shallow perched water-bearing horizon beneath the WIPP site.

A second potential source of saline fluid could be the drilling and cuttings pit used during and excavation of the Salt Shaft in 1981 (Figure 1.2). This approximately 200 ft x 300-ft pit was used to settle drill cuttings from the 12-ft diameter Salt Shaft. This waste-material area could serve as a source of the elevated concentrations of potassium found in piezometers located in the northeastern portion of the site. Upon completion of drilling of the Salt Shaft in 1982, fluid was pumped from the pit liner leaving residuum (drill cuttings and nonpumpable fluids) in the pit to dry for several months before the pit was covered with fill. Approximately two years later, a series of holes were drilled through the liner and caliche to allow any remaining fluid to drain from the cuttings. The

liner and drill cuttings were removed and the pit backfilled with caliche and compacted just prior to the construction of the Engineering Building in 1990.

4.3 Hydraulic Behavior of the Units Underlying the WIPP Site

The Exhaust Shaft was constructed and lined between 1983 and 1985. During that time, site investigations did not report the presence of groundwater within 195 feet of the surface (Holt and Powers, 1986). During the sinking and mapping of the Exhaust Shaft the shallowest fluid production noted was from the Magenta and the Culebra Dolomite Members of the Rustler Formation. Both aquifers were instrumented with piezometers to monitor hydraulic heads. In addition, the Dewey Lake, the Tamarisk and the unnamed lower member of the Rustler Formation as well as the contact between the Rustler/Salado Formations were instrumented with piezometers to monitor the hydraulic heads in those stratigraphic units. Figure 4.5 provides a diagram of the location and depth of the gauges installed in the Exhaust Shaft in units of feet and meters below the top of the collar. For 1985 through 1998, the total head values in the Dewey Lake Formation, four members of the Rustler Formation, and the Rustler/Salado contact are all significantly lower than the Santa Rosa Formation (GAR, 1998). The data indicate that neither the Dewey Lake Formation nor any member of the Rustler Formation is a source of the fluid in the Santa Rosa and that recharge of the Santa Rosa must be from above (i.e., a result of surface or near-surface events).

During the mapping of the Air Intake Shaft late in 1988, Holt and Powers (1990) noted that the shaft walls were wet in the basal sandy siltstones of the Santa Rosa Formation at a depth of 51.5 feet (33 feet below plenum + 18.5 feet of plenum) (elevation of 3,358.5 ft amsl). They suggested that the water was accumulating in the Santa Rosa sandstones that were overlying the Dewey Lake siltstones. Powers (1986) did not report any water present in the Santa Rosa during mapping of the Exhaust Shaft in 1984 (DOE, Jan. 1997).

A series of boreholes were drilled in 1979 by Sergent, Hauskins & Beckwith (SHB) (1979) for design of surface facilities. Fifty-four boreholes were drilled to depths of up to 902 feet for foundation and design evaluation of the near-surface stratigraphy at the WIPP (Sergent, Hauskins & Beckwith, 1979). Fifty-two of the boreholes were drilled to depths of less than 100 feet. These drill holes intersect the area where water is presently found. No groundwater was found present in the Santa Rosa or in any of the shallow surface rock units. All these factors combine to provide strong evidence that the fluid in the vicinity of the Exhaust Shaft started to accumulate sometime between 1984 and 1988.

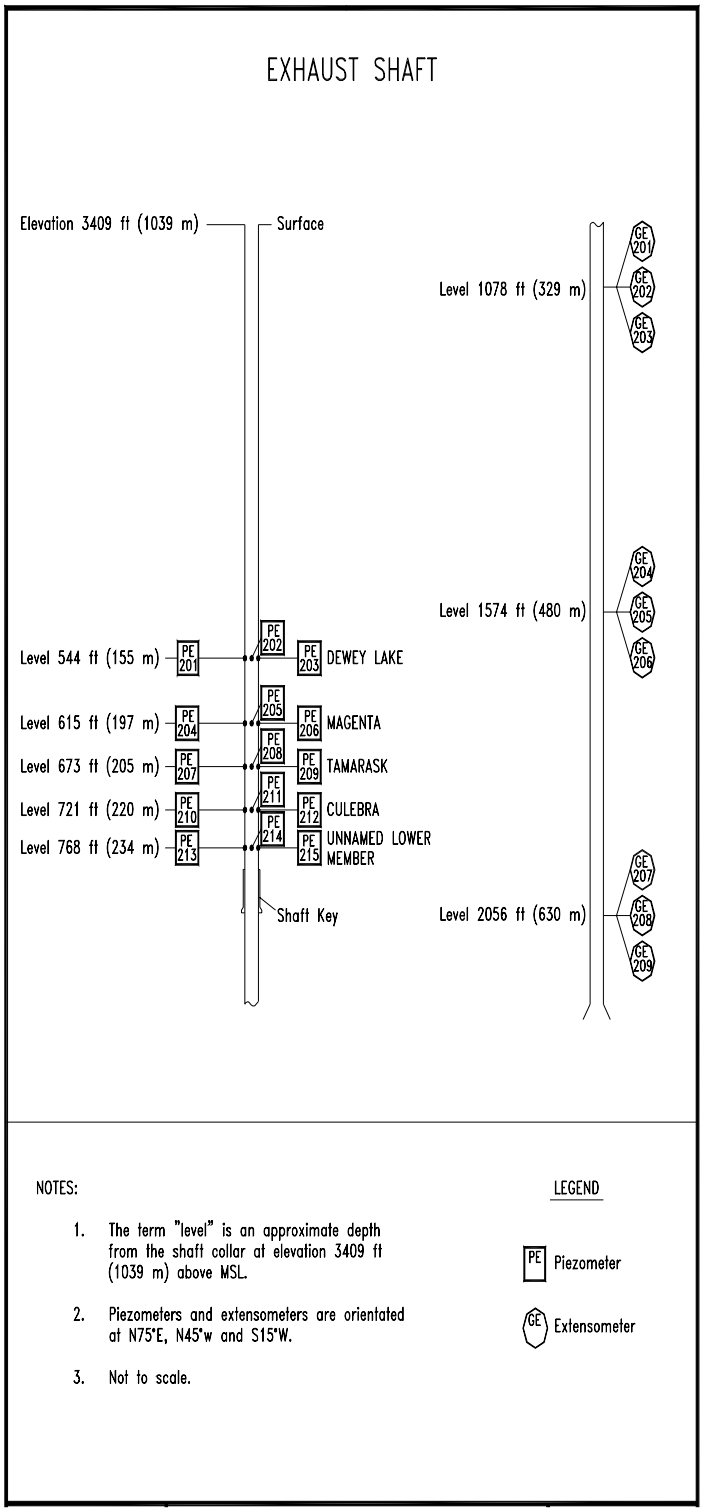

Figure 4.5 - Exhaust Shaft Instrumentation

4.4 Exhaust Shaft Flow Data

Water enters the Exhaust Shaft through two paths. First, water may enter the Exhaust Shaft through cracks or construction joints in the shaft liner. Depending on operating conditions, this water can fall down the shaft into the catch basin, be absorbed into the shaft wall, or be captured in the airflow and expelled into the atmosphere through the fans. A second source of water in the shaft involves the cooling of warm moisture laden air from the WIPP underground facility as it rises up the Exhaust Shaft. As air is cooled to the dew point, water begins to precipitate. Again this water can flow down the shaft wall into the catch basin, be absorbed into the shaft wall, or carried by the ventilation system.

When fluid was detected leaking into the Exhaust Shaft in 1995, a catch basin was designed and installed at the base of the Exhaust Shaft to intercept and prevent water from draining into the Waste Shaft sump. The catch basin consisted of two 1' x 9' x 28' polyethylene reservoirs placed at the base of the Exhaust Shaft. Fluid has been removed on an as-needed basis from the Exhaust Shaft Catch Basin since March 1996. Figure 4.6 is a plot of the volume of water removed periodically from the catch basin. In some instances, due to the ventilation configuration and the relatively dry conditions and low humidity, no water may be pumped from the catch basin for several weeks or more. At other times as much as 1000 gallons or more may be pumped out during short periods. Figure 4.7 is a plot of the total volume of fluid removed from the Exhaust Shaft catch basin between March 1996 and October 1998. Based on the plot, approximately 40,000 gallons have been captured by the catch basin during the approximate 900-day monitoring period.

Figure 4.7 represents only that portion of fluid collected in the catch basin and not subsequently evaporated from the basin. It is important to understand that the 40,000 gallons of fluid that has been removed from the catch basin does not reflect the total quantity of water entering or created in the shaft. Airflow and evaporation can significantly affect the quantity of water carried out through the exhaust-ventilation system. Figure 4.8 illustrates the impact of reduced airflow on the accumulation of fluid in the catch basin. The normal operating mode for the ventilation system is two main fans operating at 425,000 cfm. The second mode is the reduced-mode operation, where only one main fan operates: 1-main fan at 260,000 cfm or 1-Exhaust Filter fan at 80,000 cfm. Reduced mode operation is most frequently used during weekend and nonwork hour operations. The third mode is the power outage mode during which time all the ventilation fans are off for a period of time. Figure 4.8 indicates that fluid flow into the catch basin is associated with power outages, when the fans are off and the airflow through the shaft is minimal. During this time, water drains into the shaft, down the shaft walls and into the catch basin unretarded. Figure 4.8 also indicates that there are periods during reduced-mode operations that fluid does not accumulate in the catch basin (Appendix 3).

4.5 WIPP Site Precipitation Data

Figure 4.9 is a plot of precipitation data collected from the WIPP site weather station between January 1996 and October 1998. The WIPP site precipitation is highly variable. The data indicate that most commonly there are dry winters and wetter summers. Between January and December 1996, the total rainfall amounted to 11.32 inches, between January 1997 and December 1997, 20.80 inches, and between January 1998 and October 1998, 5.7 inches. The average rainfall for southeastern New Mexico is less than 10 inches per year (Appendix 4).

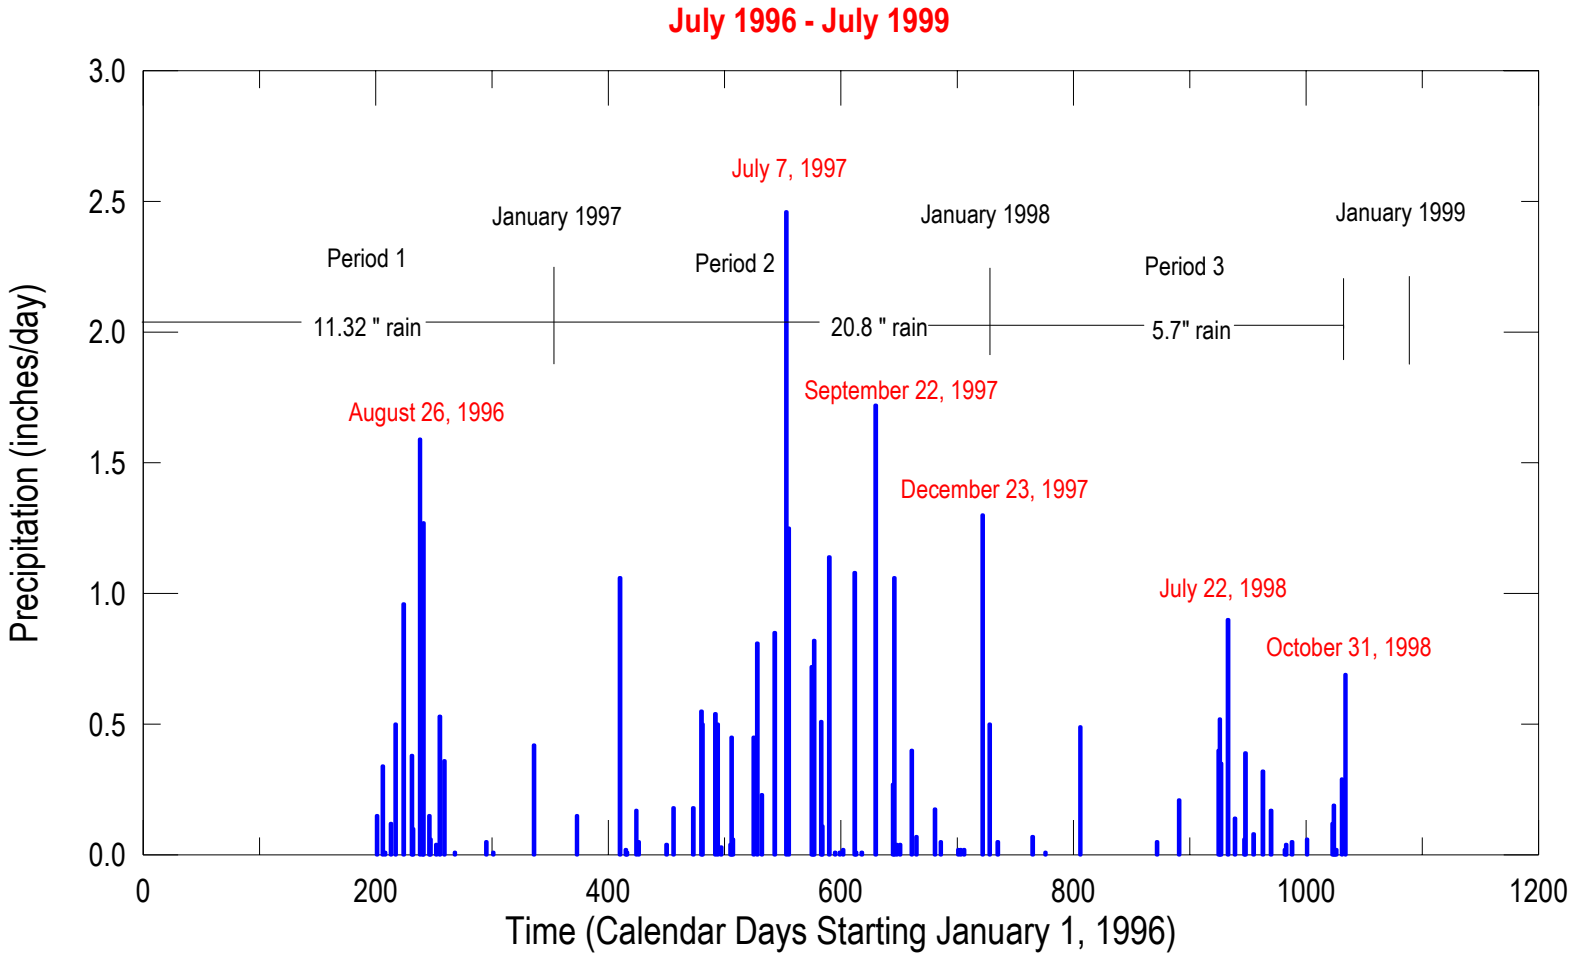

Figure 4.9 - Daily Precipitation Measured at the WIPP Site Weather Station

5.0 DISCUSSION

This section summarizes the evidence concerning the original occurrence of perched water in the Santa Rosa Formation. As noted in Section 4.3 there were no reports of fluids in either the Santa Rosa or any other shallow surficial horizon during the drilling of the shallow drill holes reported by SHB (1979) or during the mapping of the Exhaust Shaft by Holt and Powers in 1984. Further, there were no significant quantities of shallow groundwater noted at the WIPP site until the drilling and mapping of the Air Intake Shaft in 1988 (Holt & Powers, 1990). This implies that the water presently found in the Santa Rosa Formation is an artifact of post-1984 event(s). Recent recharge is supported by the extreme variability in salinity and the local potassium-rich waters. Due to the terrigenous nonevaporative sedimentary composition of the Santa Rosa and the overlying units, there is no mechanism for high-saline waters to occur naturally near the surface in this locality.

It is clear from examination of the pressure data collected from gauges installed in the Exhaust Shaft (Section 4.4) that none of the underlying water-bearing units in the Dewey Lake, Rustler, or Salado Formation contribute to the fluid in the Santa Rosa. The Dewey Lake Formation, the Magenta and Culebra dolomites (the principle water-bearing units in the Rustler Formation), and the Rustler-Salado contact all have lower head values than the groundwater in the Santa Rosa. Therefore, the water in the Santa Rosa Formation is most likely derived from some source(s) at or near the surface.

Water-level data (Section 4.1) indicates that water levels in the Santa Rosa Formation rose 2-4 feet between January and December 1997. During that time rainfall totals amounted to over 20 inches, twice the seasonal average. Water-level data also indicates that there were no significant changes in water levels between January and October 1998, a period during which WIPP site rainfall amounted to only 5.7 inches of rainfall, slightly more that ½ the seasonal average. These data are limited but are consistent with rainfall as a probable source of recharge to the Santa Rosa Formation in the WIPP locality.

The relationship of meteorological condition to precipitation in the Exhaust Shaft and the effect of this on the quantity of water accumulating in the catch basin is unclear. Figure 5.1 is a plot comparing precipitation and catch-basin flow data collected between March 1996 and October 1998. There is an indication that the volume of fluid removed from the catch basin is related to the amount and timing of precipitation and higher levels of relative humidity. However, this relationship is not clearly defined and will require additional data in order to establish statistically significant trends.

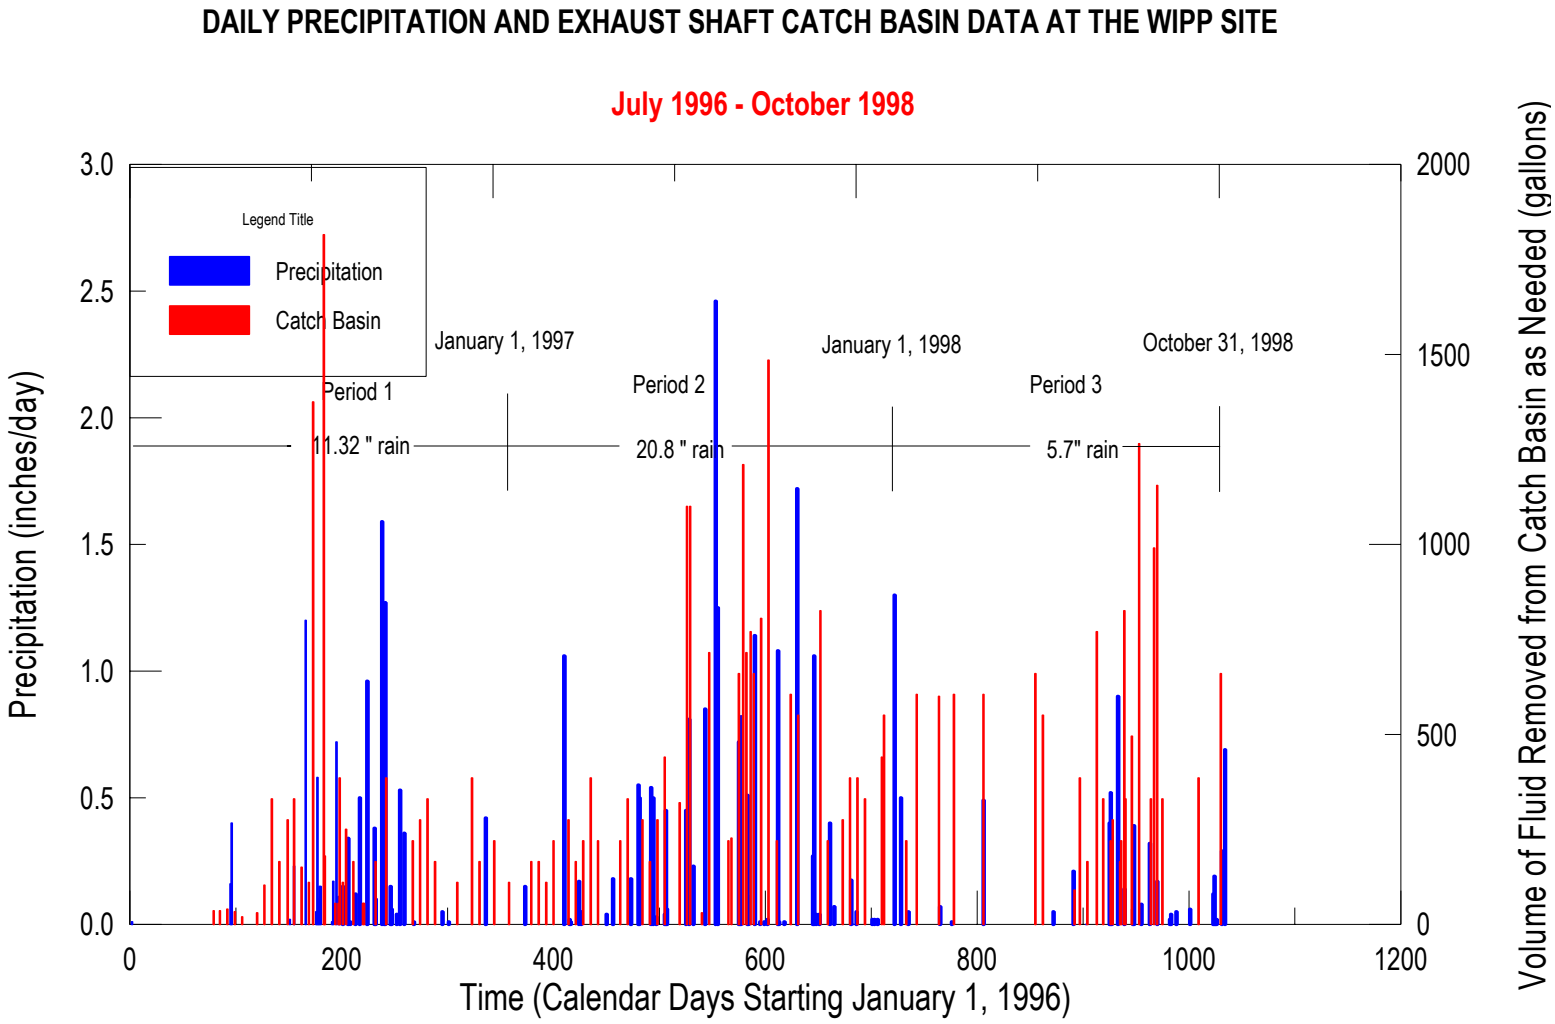

Figure 5.1 - Precipitation and Exhaust Shaft Catch Basic Flow Data

The primary factor controlling fluid flow into the catch basin is Exhaust Shaft airflow as identified in Section 4.4. During power outages and reduced-mode operations, the volume of fluid draining into the catch basin increases. Over 70 percent of the volume of fluid collected in the catch basin can be attributed to power outages. Fluid does not necessarily accumulate in the catch basin during reduced-mode operations. There are numerous periods in which no fluid was collected during reduced mode (Section 4.4) suggesting that other factors, such as the shaft humidity, may also be significant contributors to the total volume of fluid accumulating in the catch basin.

Based on water quality, indicated by total dissolved solids (TDS), the Santa Rosa fluid can be characterized by three principle groupings. The first group is highly saline with TDS values ranging from 70,000-170,000 mg/L, includes piezometers PZ-3, PZ-5, PZ-9 and PZ-1, located in the northeastern and central section of the site. The second group, with TDS values ranging from 20,000 to 70,000 mg/L, includes piezometers PZ-2, PZ-4, PZ-6, PZ-7, and PZ-11 are located in the northwest and central section of the site. The third group, with TDS values ranging from 0-20,000 mg/L and consisting of wells C-2505, C-2506, and C-2507 and piezometers PZ-10 and PZ-12, is located in the southern section of the site.

Group 1 is highly saline, dominated by chloride and sodium ions and elevated potassium ions. The area represented by these piezometers are situated adjacent to the North Salt Storage Area and near the former drilling and cuttings pit located just east of the Salt Shaft (Section 4.2). Both locations have readily available sources of sodium and chloride. Water affected by interaction with the former drilling and cuttings pit is also likely to have elevated potassium concentrations.

The area represented by the Group 2 piezometers is located adjacent to the saltwater evaporation pond in the northwestern corner of the site. Piezometers PZ-4, PZ-6, PZ-7 and PZ-11 are located west and up-gradient from the central Group-1 piezometers. Rainfall runoff from the north salt storage area drains into the evaporation pond. The concentrations of salts in the retention ponds are more dilute due to sheet runoff effects in which there is little interaction between the water and the surrounding materials. In addition, a significant amount of runoff comes from areas without any available salt. It should also be noted that dilution may be a factor changing solutes in many places.

Group 3 piezometers are located next to three storm-water retention ponds on the south and southwestern portion of the site and adjacent to the Exhaust Shaft (Figure 1.2). The ponds receive runoff from the site. Analyses of samples collected from these basins indicate that these waters are low in TDS. The wells located in the southern portion of the site have significantly lower TDS than any other wells and piezometers.

The history of the drilling of the shafts, the construction of the retention ponds, and the salt storage area drilling and cuttings pit at WIPP provides important insight concerning the relationship between the hydrology and the water chemistry within the Santa Rosa Formation. Water-level data from the Santa Rosa (Figure 4.1) indicates that the Salt Water Evaporation Pond area has the highest recorded head values across the site facility area suggesting that the pond is a primary source of recharge to the Santa Rosa.

Lines of equipotential water level (Figure 4.1) indicate that water moves radially away from the Evaporation Pond near PZ-7. The water quality and the equipotential water-level surface map (Figure 4.4), indicates that the highest head values are located in the northwest portion of the site, while the highest TDS values are located in the central and northeastern portion of the site. The high concentration of TDS in the central and northeastern portion of the site appears to be contrary to flow across the site suggesting that the high TDS concentrations are attributable to impacts other than the evaporation pond. The two most likely factors affecting the TDS concentrations in the Santa Rosa within the WIPP site facility area are the north salt storage area and the Salt Shaft drilling and cuttings pit. Salt concentrations appear to increase from the northwest to the central portion of the site as water in the Santa Rosa approaches the fringe of the Salt Shaft drilling and cuttings pit. As water in the Santa Rosa migrates further to the south it mixes with fresher water recharged by the three essentially fresh-water retention ponds located to the south. However, the order of magnitude difference in TDS from the center of the site to the southern-boundary area can not be achieved just by recharge from the retention ponds because there is no mechanism to reduce the total amount of chloride. Therefore, given the potential gradient, it can be assumed that the high TDS water that is migrating to the south and southeast will eventually flow into the area south of the Exhaust Shaft.

At the WIPP the Santa Rosa behaves as an unconfined aquifer. This is based on storativity values calculated from pumping test data collected from C-2505 and C-2506 ranging from 1.1 E-2 and 9.38 E-3 in February and March 1997 (Westinghouse, 1997). Unconfined aquifers typically have storativity values greater than 1.0 E-3.

Hydraulic tests were performed in every piezometer and well except PZ-3, and PZ-8 (dry hole). Results of those tests provided hydraulic conductivity values ranging from 2.11 E-5 to 5.88 E-8 m/s. Tests indicate that PZ-1, PZ-2, PZ-3, PZ-4, and PZ-5, C-2505 and C-2507 are capable of sustaining pumping rates of no more than 0.5 gpm for extended periods of time. On the other hand PZ-6, PZ-7, PZ-10, PZ-11, PZ-12, and C-2506 can sustain pumping rates of over 0.6 gpm. Some wells such as PZ-6, PZ-10, and PZ-12 can sustain pumping rates in excess of 1.0 gpm for extended periods of time.

6.0 CONCLUSIONS

6.1 Assessment: October 1997 through October 1998

During the twelve-month period extending from October 1997 through October 1998, water-level measurements in 15 wells monitoring the fluid level in the Santa Rosa Formation remained essentially unchanged. Drilling, pumping test, water quality, water level and precipitation data indicate that the Santa Rosa is an unconfined water-bearing horizon perched on top of the Dewey Lake Formation. Water level and precipitation data suggest that following extended periods of high rainfall, fluid levels in the Santa Rosa increase (October 1996-October 1997). However, during periods of low rainfall, fluid levels in the Santa Rosa do not increase (October 1997-1998). Pressure data collected from piezometers located in the Exhaust Shaft from the Dewey Lake and

Rustler Salado Formation indicate that there is no apparent hydrologic communication between the Santa Rosa Formation and water-bearing formations located stratigraphically below the Santa Rosa. Data suggest that rainfall runoff is a primary source of recharge to the Santa Rosa Formation.

An equipotential water level surface map of the Santa Rosa Formation at WIPP indicates that there is a potientiometric high located near the Salt Water Evaporation Pond in the vicinity of PZ-7. The water level at PZ-7 is approximately 3.5 feet higher than any other well monitoring the fluid levels in the Santa Rosa. Again flow from west to east isn't the only possibility across the northern part of the WIPP site surface facilities. Water flows radially from the PZ-7 area. In the northern portion of the site, fluid flows primarily from west to east. In the west and central portion of the site, fluid flows to the south and southeast. The areal extent of the fluid in the Santa Rosa at WIPP is significantly larger than the present 80-acre investigative area, but without drilling and additional testing there is no way of determining the areal extent of perched groundwater in the Santa Rosa.

Water-quality data indicates that the water chemistry in the Santa Rosa has been relatively stable over the past 12-month period. The water chemistry in the Santa Rosa appears to be dominated by two factors. The first factor involves rainfall runoff draining into retention ponds that provide a source of recharge to the Santa Rosa Formation. The second factor involves the introduction of salts from the Salt Storage Area, the Salt Shaft Drilling and Tailings Pit, and brine disposal in the Salt Storage Retention Pond and salt-disposal-mound moat.

Exhaust Shaft flow data indicate that approximately 40,000 gallons of fluid was collected from the catch basin between April 1996, when the basin was installed, and October 1998. Examination of precipitation data and Exhaust Shaft basin collection data appears to show that as both precipitation event frequency and amount increase, flow into the catch basin increases. Since fluid quantities removed from the catch basin appear to depend on fluid leaking into the shaft, the condensation and evaporation of moisture laden air carried by the ventilation system, and ventilation system operation, fluctuations in quantity is probably a complex function of meteorological and operations factors.

6.2 Conceptual Model

In the facility operations area, the Santa Rosa Formation is a thin erosional wedge typically less than 40-feet thick that pinches out to the west of the WIPP site. The Santa Rosa consists of a reddish-brown siltstone and fine-grained sandstone. The Dewey Lake consists of reddish-brown mudstone, claystone and interbeded sandstone. The Santa Rosa Formation is overlain by the Gatuña Formation; a poorly sorted fine-grained sandstone.

Hydrologically the Santa Rosa Formation behaves as a low permeability unconfined aquifer perched on the Dewey Lake Formation. Hydraulic conductivity values for the 15 wells drilled into the Santa Rosa ranges from 2.0 E-5 to 2.6 E-8 m/s. The wells are

capable of producing at rates of about 0.3 to 1.0 gpm. The estimated storativity value is 1.0 E-2. This perched unconfined aquifer covers an area of at least 80 acres in size and is probably significantly larger. The Dewey Lake Formation locally is the lower confining unit. No water is present in the upper portions of the Dewey Lake at the site-facility area, although water can be found at the base of the Dewey Lake Formation in WQSP-6 located over a mile to the southwest of the WIPP site facility. The Gatuña is permeable, capable of transmitting significant quantities of water to the Santa Rosa from the surface.

The potentiometric fluid-pressure high is located in the northwest corner of the WIPP site at PZ-7 near the Salt Water Retention Pond. The Salt Water Retention Pond appears to be a primary recharge area draining an area approximately 15-18 acres in size (including the Salt Storage Area). During major rainfall events, significant quantities of water are available for infiltration from the surface through surficial materials and the Gatuña into the Santa Rosa. Two other areas of potential recharge are the retention pond at PZ-10 and two retention ponds adjacent to PZ-12 in the southern portion of the site facility area.

At present there are at least two boundary conditions. First, there is a no-flow boundary located west of PZ-8 as evidenced by the dry hole in PZ-8 and the presence of fluid in PZ-9. And two, there is a sink located at the Exhaust Shaft as fluid seeps into the shaft.

PZ-7 has a potentiometric head value of 3377.74 feet amsl, 3.5 feet higher than any other well location. The lowest potentiometric head value is found at PZ-12 with a head value of 3355.59 feet amsl, 22 feet lower than PZ-7. Fluid appears to move radially away from the Salt Water Retention Pond near PZ-7 toward the WIPP site. In the northern section of the site fluid moves to the east. In the western and central portion of the site fluid moves to the south and southeast.

6.3 Areas for Further Investigation

The conceptual model in section 6.2 appears to account for the pattern presented by the observed data. There are two areas however, where additional information would be of value. The first concerns hydrologic data in and near the Salt Storage Area, and the second concerns the definition of the areal extent of the water in the Santa Rosa Formation.

The majority of the salt mined and excavated from the underground has been deposited north of the WIPP site in the North Salt Storage Area. Data collected during drilling, testing, and water-quality sampling of wells penetrating the Santa Rosa indicate that the Salt Storage Area may have an impact on the site hydrology and groundwater quality. At this time, except for piezometer PZ-7, there are no wells present in or near the Salt Storage Area. Since changes within that area might impact site environmental performance, installation of one to two monitoring wells in and near the Salt Storage Area should be considered. Water-level data from the piezometers would provide data to refine the site hydrologic conceptual model. Water-chemistry data would be useful in

delineating differences between waters dominated by interaction with the Salt Storage Area or the Salt Shaft Drilling and Tailings Pit.

If both the extent of the water present in the Santa Rosa and the flow dynamics were known on a larger scale, then the uncertainty in defining the boundary conditions at the WIPP would be reduced. At present, there is a no-flow boundary near PZ-8 (dry hole). There is also a boundary condition at the Exhaust shaft. Several wells located north, south and west of the site would better define boundaries in those directions and aid in development of better numerical flow models.

Development of a numerical flow model of the Santa Rosa Formation near the WIPP Exhaust Shaft would be helpful for quantifying the effectiveness of any proposed schemes to stop or decrease the amount of fluid seeping into the shaft. One approach might be the use of the USGS MODFLOW model and the graphical user interface Groundwater Vistas. The areal extent of the model would be sufficient to reduce the effect of boundary conditions (at the edge of the model) on the results of the modeling. The model could be used to investigate the potential effects of seepage from salt piles and evaporation ponds, and would focus on evaluating proposed and potential remedies to reduce or stop inflow into the shaft. Proposed remedies might include installation of extraction wells near the shaft and for reduction of seepage from evaporation ponds. The model would focus on evaluating proposed and potential remedies to reduce or stop inflow into the shaft. The model would provide insight into the sensitivity of the infiltration components on the flow into the shaft. In addition, the model could be used to develop a potential understanding of overall flow dynamics in the Santa Rosa and may be helpful for identifying other potential remedial alternatives.

Appendix 1 - Personal Communication from Dr. Dennis Powers Concerning the Location of the Santa Rosa Sandstone in Boreholes C-2505, C-2506, and C-2507

During drilling of C-2505, C-2506, and C-2507, the top of the Santa Rosa Formation was placed at depths of 48.8 ft, 48.2 ft, and 39.5 ft below ground surface (bgs), respectively (Powers and Martin, 1996, *in* Intera, 1996). Based on the rocks recovered from C-2505 and subsequent drilling of the PZ holes at the site (Powers, 1997, *in* Intera, 1997), the top of Santa Rosa should better have been placed at 39.6 ft bgs in drill hole C-2505. This is more consistent with the record of the exhaust shaft (Holt and Powers, 1986) as well. For C-2506 and C-2507, the top of Santa Rosa is likely above the initial coring depths for each drill hole.

As a consequence of these changes, several figures in Powers (1997, *in* Intera, 1997) will change modestly. Figures 11 and 12, mapping the elevation of the top of the Santa Rosa in detail, will show a smaller area lower than 3,365 ft msl and the contour for 3370 ft msl will be south of the exhaust shaft area. Figures 13 and 14, mapping the thickness of the Gatuña Formation, will show some corresponding changes around the shaft area, with thickness reduced by about 9 ft. The general shape of the contours is not changed, nor are any conclusions about the formation of these units changed.

Basic stratigraphic data for each drill hole in the PZ series, C- series, and exhaust shaft are included in Table A1 for convenience.

4/20/98	0	1-700 fan
4/27/98	0	1-700 fan
5/4/98	660	Saturday 0600-1730 no fans. Rest of weekend 1-860 fan.
5/11/98	550	Saturday 9.5 hours no fans. Rest of weekend 1-860 fan.
5/18/98	495	1-860 fan. Work was being done on the new 700c fan connection
5/20/98	110	Flow reduced overnight to 1-860 fan
6/1/98	330	1-860 fan all weekend
6/10/98	90	1-860 fan overnight 6/9/98
6/15/98	385	1-860 fan all weekend
6/22/98	165	Sunday 1-860 fan in service 700b serviced 0335 for vibration alarms
7/1/98	770	1-860 fan until 0745, 1700 fan rest of day.

Appendix 3 - Exhaust Shaft Catch Basin and Ventilation Conditions Between July 1997 and October 1998

Date (mm/dd/yy)	Volume Removed From Catch Basin	Comments Weekend Status
7/7/98	330	1-700 fan all weekend
7/14/98	220	Ventilation outages for 700 C installation
7/16/98	275	Ventilation outages for 700 C installation
7/23/98	165	Running 1-700. Extremely humid conditions.25% RH per CMR
7/24/98	220	Power outage to support 700c fan installation
7/27/98	825	Power outage to support 700c fan installation
7/28/98	330	Power outage to support 700c fan installation
8/3/98	495	1-860 fan for 700c fan installation
8/10/98	1265	Friday @ 1500 1-fan 860 Saturday at 0525, all fans secured, Sunday at 1600, 1-860 fan support for fan installation
8/24/98	990	8/22/98 700A fan secured at 0545, no fans running 8/22/98 until 1300. 860A was started, ran remainder of the weekend.
8/27/98	1155	On Wednesday, 8/26/98, 700B fan secured at 1800 for high vibration. 1-860 fan started shortly thereafter. At 0749 Thursday, 8/27/98, 700A fan started. Ran most of day except for some 700C tests. Humidity has been high.
9/1/98	330	1-700 fan operating except for short periods during testing of 700c. Weather conditions during this period have been extremely humid.
10/5/98	385	On Saturday 10/03/98, at 1400 flow was reduced to 1-860 fan by an unplanned shift to filtration. The remainder of the weekend was 1-860 fan. On Monday morning at approximately 0800, flow was reestablished with 1-700 fan.
10/26/98	660	On Friday, 10/23/98 at 2400 flow was reduced to 1-860 fan. The 860 fan was secured at 0800 on Saturday 10/24/98 until 1700. One fan was started at 0700 on Monday 10/26/98
