ACKNOWLEDGEMENTS

The work reported in this document has been a joint effort of engineers and scientists at the International Technology (IT) Corporation, working out of their Albuquerque and Carlsbad, New Mexico, offices, and the staff of the Geotechnical Engineering Section of Westinghouse Electric Corporation at the Waste Isolation Pilot Plant (WIPP). Most of the underground work has been done by the technicians and drillers of the Westinghouse Electric Corporation.

Dwight Deal provided the overall direction and coordination of this work and authored Section 2, a discussion of brine inflow data. Appendices A and B, which contain brine inflow data and graphical representation of that data, were prepared by Dave Belski, Jeffrey Clark, and Merrie Martin. Rich Abitz, assisted by Jeffrey Clark, is responsible for Section 3 and Appendix C, brine geochemistry. Mark Crawley planned, implemented, and reduced the data from the hydrologic testing of the fractured zone beneath the repository excavations. The tests were installed and run with the assistance of Westinghouse field hydrologist Ron Richardson and technicians Mel Balderrama, Dave Belski, Steve Osmanski, and Steve Azzinaro. Section 4, describing the hydrologic testing, was jointly authored by Mark Crawley and Dwight Deal.

Dave Belski, a senior Westinghouse Electric Corporation technician at the WIPP, led the site support of the Brine Sampling and Evaluation Program (BSEP) at the WIPP site. Dave collected most of the samples, wrote the field notes, packaged samples for shipping, did the routine QC, and maintained the records and files.

Roy Cook, manager of the Geotechnical Engineering Section for Westinghouse Electric Corporation, not only provided overall management responsibility for the Geotechnical Engineering Section and helpful editing of this report, but also contributed insightful and helpful suggestions on the interpretation of the data, interactions between rock mechanics and brine flowage, and suggested possible future directions for the BSEP investigations.

EXECUTIVE SUMMARY

The data presented in this report are the result of Brine Sampling and Evaluation Program (BSEP) activities at the Waste Isolation Pilot Plant (WIPP) during 1989. These activities, which are a continuation and update of studies that began in 1982 as part of the Site Validation Program, were formalized as the BSEP in 1985 to document and investigate the origins, hydraulic characteristics, extent, and composition of brine occurrences in the Permian Salado Formation, and seepage of that brine into the excavations at the WIPP. Previous BSEP reports (Deal and Case, 1987; Deal and others, 1987; Deal and others, 1989) described the results of ongoing activities that monitor brine inflow into boreholes in the facility, moisture content of the Salado Formation, brine geochemistry, and brine weeps and crusts. The information provided in this report updates past work and describes progress made during the calendar year 1989. In addition, the 1988 BSEP Report (Deal and others, 1989) presented results of bacteriological studies, downhole video camera studies, geophysical investigations, and near-field versus far-field brine flow modeling.

During 1989, BSEP activities focused on three major areas to describe and quantify brine activity: (1) monitoring of brine inflow, e.g., measuring brines recovered from holes drilled upward from the underground drifts (upholes), downward from the underground drifts (downholes), and near subhorizontal holes, (2) further characterizing the brine geochemistry, and (3) testing the hydrologic properties of the local fractured zone that develops immediately beneath the WIPP excavations, i.e., performing pump tests on 3.0 m deep drillholes through the fractured zone below the facility drifts, including Marker Bed 139.

Monitoring Brine Inflow. 1989 results of the relative amounts of brine seepage between upholes, downholes, and subhorizontal holes substantiate trends found in earlier reports. Typically, upholes produce much smaller amounts of brine than the downholes and tend to cease production after 2 to 3 years. Subhorizontal holes continue to have very low brine inflow rates. Subhorizontal holes older than 2.5 years remain dry.

Brine recovery from downholes substantially differs from holes drilled in other orientations. Downholes tend to produce brine over extended periods of time and sometimes show increased seepage rates for several months to a year or more. Closely spaced holes may have seepage rates, volumes, and brine levels varying by two orders of magnitude or more. Some holes, such as the one in Waste Storage Panel 1 at S1950-E1320, receive water

introduced to the underground from sources other than the Salado Formation. Much of the brine in downholes throughout the facility appears to be a mixture of Salado Formation brine and construction water spread upon the floors for the purpose of dust control or roadway consolidation.

Characterization of Brine Geochemistry. Geochemical analyses of the brine has proven to be an extremely useful tool in understanding the modes of brine occurrence in the rock and the means by which brine enters the excavations. Anomalous compositions of brines recovered from upholes can be accounted for by evaporation due to the slow accumulation of the brine. Analyses of brines coming from many of the downholes indicate that some of the brines are not indigenous to the Salado Formation, but rather have been introduced during the course of mining operations for purposes of dust control and roadbed consolidation. Brine samples contaminated with construction water can be identified by a distinct geochemical signature.

Variation in the composition of indigenous brines recovered from downholes suggests spatial heterogeneity exists, which implies mixing and fluid homogenization is limited within the Salado Formation at the WIPP repository horizon. WIPP brines are chemically distinct from the formational waters in the overlying Rustler Formation or underlying Castile Formation. This implies an absence of a large-scale, vertical migration between WIPP brines and these formations.

Major-element compositions of indigenous WIPP brine suggest an origin from evaporating seawater, modified by diagenetic reactions involving gypsum, magnesite, and polyhalite; and by ion-exchange with clay minerals. The major-element compositions of brines recovered from drillholes differ from fluid inclusions in the Salado halite. This observation indicates that the brine recovered in drillholes is largely intergranular fluid, rather than intragranular fluid which has been released by migration of fluid inclusions to grain boundaries during stress relief.

Rock-brine equilibria were evaluated using brine analyses and the speciation-solubility code EQ3NR. The modeling results indicated all WIPP brines were saturated with anhydrite, barite, fluorite, glauberite, gypsum, and halite while several brines were calculated to be saturated with celestite, dolomite, magnesite, and polyhalite. Model results agreed with the observed mineralogy in the WIPP repository and supported the contention that WIPP brines are fluids which have equilibrated with evaporite salts.

Finally, the analytical results and solubility calculations suggest a derivation of WIPP brines from near-field, intergranular fluids. Although the data do not unequivocally rule out large-scale brine migration, the time scale required for migration of the fluid through the halite of the Salado Formation would have to be greater than that required for diagenetic reactions to produce magnesite, polyhalite, and quartz. Excluding human intrusion scenarios, time constraints on fluid migration through halite after the repository is sealed and repressurized suggest that soluble radionuclides will be constrained to the near-field environment of the waste for time periods sufficient to meet regulatory guidelines.

Hydrologic Testing of the Fractured Zone Concentrated in Marker Bed 139. A short-duration hydraulic test was conducted in the macrofracture zone that develops beneath the floor of the underground facility. The macrofracture zone develops a few years after excavation and is concentrated within, but not limited to, Marker Bed 139, a brittle anhydrite unit. A standard pumping drawdown hydrologic test was conducted to characterize the distribution of fractures and saturation and to obtain transmissivity and storage coefficients for the zone of macrofractures, most of which occur within 3 m of the excavations.

The hydrologic tests were conducted in the area of the intersection of the S-90 and W-620 drifts, near the bottom landing area of the Air Intake Shaft (AIS). This site was selected because the zone of macrofracturing became saturated in this area when 488,000 liters of brine were introduced during the construction of the AIS. Ten holes, 3 m long were drilled from the floor of the drift through Marker Bed 139.

Preliminary test results confirmed that, at the time of the tests, the macrofracture zone was concentrated in Marker Bed 139 and was saturated in much of the area around the AIS station. The fractured zone was found to be locally confined.

Preliminary testing also revealed that the fluid levels in the test holes are independent of the fluctuating fluid levels in the AIS sump, at least for the several days of these tests.

The results of the pump test indicate that there are separate saturated fracture systems within Marker Bed 139. There is more enhanced permeability and interconnected fracturing beneath the S-90 W-620 drift intersection than further east along the S-90 drift. The Jacobs, Theis, and Theim methods were used to determine transmissivity and storage coefficients. The

transmissivities for all holes are 0.1 to 0.2 m²/day. Storage coefficients ranged from 1.04 x 10⁻⁴ to 1.04 x 10⁻³.

The transmissivities determined in this test are several orders of magnitude higher than those measured elsewhere in Marker Bed 139. This indicates that the zone of floor fractures can become highly permeable as the damaged rock zone decouples from unfractured or microfractured rocks within that part of the Disturbed Rock Zone (DRZ) close to the excavations. The permeability of Marker Bed 139 involved in the fracturing increases dramatically with time in the vicinity of excavated drifts and rooms.

The pumping drawdown test provided valuable data on the hydrogeologic characteristics of Marker Bed 139 in the area tested. This test had a limited scope and should be considered as a preliminary attempt to characterize hydrologic conditions in the macrofractured zone within the marker bed. Additional tests are recommended to adequately quantify the distribution of permeability, storativity and fracture geometry.

These additional data should be compiled to generate a comprehensive three-dimensional computer solute transport model of potential contaminant migration in the zone of macrofractures. This modeling is of importance to: (1) performance assessment, (2) the migration pathway scenario as modeled in the SEIS (U.S. Department of Energy, 1990a) and the No Migration Variance Petition (U.S. Department of Energy, 1990b), and (3) the design of engineered seals and plugs to be installed prior to the decommissioning of the repository.

1.0 INTRODUCTION

The Waste Isolation Pilot Plant (WIPP) is a Department of Energy (DOE) research and development facility established to demonstrate the safe disposal of defense generated radioactive wastes in the United States. The WIPP mission consists of two parts: (1) to demonstrate the safe handling and disposal of transuranic (TRU) waste in bedded salt, and (2) to create a research facility for in situ examination of technical issues related to the emplacement of defense related transuranic waste in bedded salt.

The WIPP facility is located approximately 42 km east of Carlsbad, New Mexico (Figure 1-1). The underground portion of the facility (Figure 1-2) is located approximately 655 m below the surface in the Salado Formation, an evaporite sequence approximately 1000 m thick (Figure 1-3). An extensive program of site characterization and validation has been conducted over the past 13 years (1976 to 1989). Initial studies are summarized in the WIPP "Geological Site Characterization Report" (Powers and others, 1978) and the WIPP "Preliminary Design Validation Report" (Bechtel National, Inc., 1983). Additional site investigations are being conducted as part of a continuing program to refine the understanding of the site-specific geology. The hydrogeological activities of the Brine Sampling and Evaluation Program (BSEP) are part of these investigations.

The purpose of the BSEP is to investigate the origin, hydraulic characteristics, extent, and composition of brine in the Salado Formation excavations at the WIPP repository horizon. Although the repository horizon is considered dry, brine is observed to weep from exposed surfaces and seep into drillholes placed in the underground excavations. Brine studies began in 1982 as part of the Site Validation Program (Black and others, 1983), and was formalized in 1985 (Morse and Hassinger, 1985). The data presented in this report are an update of studies previously reported (Deal and Case, 1987; Deal and others, 1987; Deal and others, 1989). To facilitate a better understanding of the presented data, readers should consult those previous reports. Detailed descriptions of the data gathering and analytical procedures, and the cautions that should be exercised when using the data presented herein are given in these earlier reports.

Activities in 1989 provide information on the amount of brine that flows into the underground (Section 2.0), the geochemical properties of the brine (Section 3.0), and the hydrologic

 (MODIFIED FROM FIGURE 1-2, DEAL AND CASE, 1987)

properties of the zone of macrofractures that develop beneath the excavations as those excavations age (Section 4.0). Other than Section 4.0, this report is an update of the 1988 Brine Sampling and Evaluation Program report (Deal and others, 1989) and further substantiates the observations and conclusions therein.

This report constitutes a permanent quality assurance record and will be retained as such as provided for in the quality assurance sections of the Geotechnical Engineering Program plans and procedures.

2.0 MONITORING OF BRINE INFLOW PARAMETERS

2.1 INTRODUCTION

Brine seepage observations in underground locations at the WIPP began as early as 1982. Brine inflow information was derived from observations and mapping of moist areas and measurements of brine seeping into holes drilled downward from the floor of the facility, upward from the back (roof) of the facility, and sub-horizontally from the rib (wall) of the facility. The locations of the BSEP observation holes are shown in Figure 2-1, which also shows the extent of the excavations that existed at the end of 1989. The underground locations where brine observations have been made as part of the BSEP are listed in Appendix A (Table A-1).

The brine accumulations in holes drilled from the WIPP underground workings and the stratigraphy of the Salado Formation have been extensively discussed in previous reports (Deal and Case, 1987; Deal and others, 1987; Deal, 1988; Deal and Roggenthen, 1989; Deal and others, 1989; and Deal and Roggenthen, 1991).

2.2 DOWNHOLES

Deal and Case (1987; Table 2-1) discussed brine inflow in 13 downholes with observations beginning in late 1984 and early 1985 and extending through August 1986. After 1.5 years, observations showed ten holes with fairly steady inflow trends, two with decreasing trends and one hole with an increasing trend. As of July 1987 (Deal and others, 1987), approximately 2.5 years of observation reflected a general decreasing trend. The ten steady trending holes were reduced to five steady holes and five with decreasing trends. The two that had been decreasing continued to decrease, and the one hole with an increasing inflow trend began to decrease. By the end of December 1988 (Deal and others, 1989), after approximately 4 years of observation, the following brine inflow trends were evident: five, 15 m holes [two in heated experimental rooms] remained steady; one was increasing; and five were decreasing. Two of the original 13 holes were pinched shut by salt creep and could no longer be sampled. December 31, 1989 marked five years of observation. Three downholes showed increasing inflow during the last two months of observation, two remained steady, and six were decreasing. Table 2-1 summarizes the most important data obtained from the downholes, with additional information in Appendix A.

Data summarized and rounded from Appendices A and B.

I = Increasing

S = Steady

D = Decreasing

2.3 UPHOLES

Upholes characteristically produce less brine and for shorter periods of time than downholes. Part of this can be attributed to greater evaporation caused by less effective sealing of upholes (Deal and Case, 1987) and loss of moisture by dispersion from the hole collar into the salt. Loss of moisture by evaporation is evident from salt crust buildup in and around most of the upholes. Chemical data (Deal and others, 1989; Abitz and others, 1990) confirms compositional differences between the brines from upholes and downholes that can be explained by partial evaporation of some of the uphole brine and concomitant precipitation of halite and other salts. The stratigraphy exposed in the upholes is slightly different from that exposed in the downholes; it is unclear whether this contributes significantly to the differences in either brine quantity or chemistry (Deal and others, 1989). Summary data for selected upholes are presented in Table 2-1 also. Only two, A1X02 and A2X02, of the nine upholes listed in 1985 continue to produce brine. Additional data are presented in Appendix A.

2.4 SUBHORIZONTAL HOLES

During 1989, eleven subhorizontal holes were drilled: one at a depth of 1.3 m; seven at a depth of 15.2 m; and three at a depth of 45.7 m. These holes were drilled as a means to investigate seepage rates and brine chemistry of the stratigraphic horizons exposed at the repository level. The holes are oriented slightly downward to accumulate brine at the end of the hole and prevent the effects of evaporation. The three, 45.7 m holes are producing measurable quantities of brine. Interpretations will be presented in a subsequent report when additional data become available.

2.5 DAMP OR WET AREAS ON FLOORS

Moist floor areas have been previously discussed by Deal and Case (1987), Deal and others (1987) and Deal and others, (1989). At present, Room G contains the only sizeable, persistently moist area in the WIPP underground facility. Seepage in Room G showed a maximum of about 0.75 liters per day in April, which declined to 0.6 liters per day by the end of 1989.

3.0 CHARACTERIZATION OF BRINE GEOCHEMISTRY

Geochemical analyses of the brine is an extremely useful tool in understanding the modes of brine occurrence in the Salado Formation and the means by which it enters the excavations. Brine samples were collected quarterly in 1989 and these analyses are presented in Appendix C. Previous work has shown that much brine was introduced during the course of mining operations for purposes of dust control and roadbed consolidation (Deal and others, 1989).

Uphole brine chemistries have been modified by partial evaporation of the brine and precipitatin of halite and/or other salts. Variations in brine composition between downholes and weeps suggests that spatial heterogeneity exists (Stein and Krumhansl, 1988). This implies that mixing and fluid homogenization has been limited within the Salado Formation at the WIPP repository horizon. The WIPP brines are chemically distinct from the formational waters in the overlying Rustler Formation and underlying Castile Formation (Deal and others, 1989; Abitz and others, 1990). This implies a lack of significant vertical migration between these formations.

Major-element compositions (Stein & Krumhansl, 1988; Deal and others, 1989; Abitz and others, 1990) of the WIPP brines suggest an origin from evaporating seawater that had precipitated carbonate minerals, anhydrite, and halite. The brine was further modified by diagenetic reactions with gypsum, magnesite, polyhalite, and ion-exchange with clay minerals. A residual fluid origin is further substantiated by the high magnesium and bromine content of the brines which differs from an origin by infiltrating groundwater dissolving the salt. The major-element compositions of brines recovered from downholes are distinct from fluid inclusions in WIPP halite (Stein and Krumhansl, 1988), hence the brine recovered from drillholes is largely intergranular fluid, instead of intragranular fluid released by migration of fluid inclusions to grain boundaries by stress relief.

Rock-brine equilibria were evaluated using the brine analyses and the speciation-solubility code EQ3NR (Wolery, 1983). Modeling indicates that all WIPP brines are saturated with respect to anhydrite, barite, fluorite, glauberite, gypsum, and halite. Several brines were calculated to be saturated with respect to celestite, dolomite, magnesite, and polyhalite (Deal and others, 1989; Abitz and others, 1990). Model results agree with the observed mineralogy at the WIPP repository; this supports the contention that WIPP brines are fluids which have equilibrated with evaporite salts.

Finally, the analytical results and solubility calculations (Deal and others, 1989; Abitz and others, 1990) suggest that WIPP brines are derived from near-field, intergranular fluids. Although the data does not unequivocally rule out large-scale brine migration, the time required for a large-scale fluid movement through the Salado halite would have to be greater than that required for diagenetic reactions which produced magnesite, polyhalite, and quartz. Excluding human intrusion scenarios, time constraints on fluid migration through halite after the repository is sealed and repressurized suggest that soluble radionuclides will be constrained to the near-field waste for time periods sufficient to meet regulatory guidelines.

4.0 HYDROLOGIC TESTING OF THE FRACTURED ZONE BENEATH THE EXCAVATIONS

4.1 BACKGROUND

This section presents the results of a short-duration hydraulic test conducted in the macrofracture zone that develops beneath the floor of the underground facility horizon at the WIPP site. The goal of this hydrologic testing program was to determine if useful hydraulic data could be obtained from the zone of macrofracturing by conducting a pumping drawdown-type hydrologic test in areas where saturated conditions were expected.

Salt deforms plastically at repository depths, creeping into newly excavated openings, creating a halo of deformation referred to as the Disturbed Rock Zone (DRZ). The deformational envelope around underground excavations in salt is characterized by: (1) an outer zone of dilatancy and microfracturing where pore pressure exceeds atmospheric pressure, and (2) an inner zone of macrofracturing where pore spaces are at atmospheric pressure (Deal and Roggenthen, 1991). The inner zone, which includes the volume of rock that has separated (decoupled) from the host rock, has been construed as the growing part of the excavation comprising the "Actual Opening" (Mraz, 1980).

Other investigations at the WIPP have focused on the hydrologic conditions in the salt near the excavations undisturbed by DRZ development (Beauheim and Holt, 1990), gas permeability within the zone of dilatancy where pore pressures are above atmospheric pressure (Peterson and others, 1985), and the theoretical development of hydrologic systems within the zone of dilatancy (Deal and others, 1989). The focus of this investigation is the hydrology of the inner zone of the DRZ (or "Actual Opening") that lies below the floor of the WIPP excavations. This zone may be a few meters thick, and contain open macrofractures up to 23 cm in width (Francke and others, 1989; Deal and Roggenthen, 1991) which, unless locally filled with brine, are essentially at atmospheric pressure. Fractures filled with brine have a local hydrostatic pressure component measured as head developed beneath the floor of the excavations, not as a hydrostatic component related to ground elevations at the surface above the excavations or to stress differences in the deforming salt.

The Salado Formation is predominantly halite, consisting of alternate sequences of halite, argillaceous halite, polyhalitic halite, clay partings 1 to 3 cm thick, clay layers, and thin anhydrite beds, as numerous horizontal discontinuities. Anhydrite beds ranging from a few millimeters to about 1 m in thickness are brittle at repository depths. As the salt deforms, the

contrast in ductility between salt and anhydrite causes preferential fracturing in the brittle anhydrite. Marker Bed 139, approximately 1 m thick located 2 m beneath the floor of the excavations, shows how local variation in stratigraphy influences the development of macrofractures. The dish-shaped fractures that normally develop beneath the floor are distorted and tend to flatten near the room center (Figure 4-1). Although the fractures concentrate within the anhydrite, especially beneath the center of drifts or rooms, they also cut the halite and other units (Bechtel National, Inc., 1986). Air-filled fractures up to 15 cm wide have developed two to five years after excavation (Bechtel National, Inc., 1986). Five years after excavation the largest observed separation is about 23 cm wide.

Some subhorizontal fracturing has been noted just above clay E, at the base of Marker Bed 139, approximately 2 m below the floor of the excavations, but no separations at clay E were noted (Bechtel National, Inc., 1986). This may be because the creeping salt deformed upward and pushed against the anhydrite to keep the clay confined.

Near the edges of rooms and drifts, fracturing tends to be concentrated in the ribs or salt above Marker Bed 139 (Figure 4-1). Ultimately, fracturing will extend into the salt below Marker Bed 139. The zone of macrofractures was expected to extend about 2 m below the floor of the excavation at this site and to extend laterally a lesser distance into the bedrock beyond the edges of the rooms. In map view, the fractured zone under investigation is expected to closely follow the plan of the underground excavations.

4.2 DESCRIPTION OF THE TEST AREA

This hydrologic test was conducted at the intersection of the S-90 and W-620 drifts 27 m south of the bottom landing area of the recently excavated Air Intake Shaft (AIS) (Figure 4-2). This location was selected because the fractured zone appears to be locally saturated with brine and exhibits some degree of interconnected fracturing. An engineered sump for seepage of Rustler Formation fluids during construction of the AIS, is located immediately north of the test site, between the pumped hole and the AIS (Figure 4-3).

4.3 PREPARATORY ACTIVITIES

The following preparatory activities were required prior to the pumping drawdown test: (1) drilling of holes; (2) equipment installation; (3) determination of initial hydrologic conditions; and (4) preliminary drawdown testing.

FIGURE 4-1. CROSS-SECTION OF FRACTURING AROUND A 4 m HIGH, 10 m WIDE WASTE STORAGE ROOM AT THE WIPP

FIGURE 4-2. MAP OF UNDERGROUND TEST LOCATION

FIGURE 4-3
LAYOUT OF HYDROLOGIC TEST SITE

4.3.1 Drilling of Test Holes

Ten holes, 3 m long and 8 cm in diameter, were drilled to a depth just past the base of Marker Bed 139 to monitor drawdown in the alcove area, along the S-90 drift, and in the W-260 drift between the AIS and the alcove (Figure 4-3). The centrally located OH-36 was designated as the hole to be pumped. The distance of the observation holes from the pumped hole are given in Table 4-1. Brine drilling fluid was required for most of the holes to reduce the amount of salt dust in order to avoid deleterious effects on delicate instrumentation that was being installed at Room Q, to the west along the S-90 drift. After drilling each hole, compressed air was used to purge fluid from the hole.

The development of macrofractures (discussed in Section 4.1) is a function of several factors, including stratigraphy, excavation geometry, and time since excavation. Fracturing tends to develop more quickly beneath wider excavations and develop first beneath the center of the excavation. The degree of fracturing increases with time, therefore the older the excavation, the more developed the fracturing.

At the test site, both the S-90 drift to the east (where holes OH-38, OH-39, and OH-40 are located) and the W-620 north (toward the AIS) are about the same age. They were excavated during the first two weeks of November 1987, approximately 17 months before this testing. The S-90 drift is 4.3 m wide while the W-620 drift is 7.6 m wide. Therefore, it was expected that fracturing would be better developed beneath the wider W-620 drift than beneath the S-90 drift.

The extreme south end of the transformer alcove was excavated on January 24, 1988, and is 2.5 months younger than the rest of the W-620 drift. Hole OH-44 is located in the alcove, but this small age difference has an insignificant effect on macrofracture development. The close proximity of OH-44 to the rib is more important as locations away from the center of the excavation are less likely to have fracturing.

The 6 m wide S-90 drift west of the test location was excavated on November 4, 1988, and is much younger than the other drifts at this location. It is unlikely that significant macrofracturing associated with the westward extension of the S-90 drift would have occurred in those five months. Therefore, it was expected that both OH-35 and OH-44 would show the least fracturing and that OH-38, OH-39 and OH-40, down the center of a 4.3 m wide drift, would show less fracturing than the other holes located in the center of a 7.6 m wide drift or in the drift intersection. The expected differences in fracturing was subsequently confirmed.

4.3.2 Equipment Installation

OH-36, OH-37, OH-38, OH-41, OH-42, OH-43, and OH-44 were instrumented with pressure transducers (Geokon model 4500-H) prior to and during the pumping test. In addition to these holes, a small bolt hole directly beneath the AIS was also instrumented with a Geokon pressure transducer. Solinst water-level detectors were used to measure fluid levels in OH-35, OH-39, and OH-40.

A Bennett model air-driven, piston pump allowed user-controlled discharge rates from approximately 4 to 284 liters per hour. This pump was capable of a very low discharge rate during the test and utilized the readily available supply of compressed air. The pumped brine was routed to two, 945 liter storage tanks that were emptied, as required, to accommodate water storage needs.

All pressure transducer data were stored in random access memory in two Geokon CR-10 remote data loggers. These data were transferred to magnetic disk using a portable computer (Tandy Model 102 laptop and a Toshiba Model 1200).

4.3.3 Determination of Initial Hydrologic Conditions

In general, the only water sources available to recharge the floor fractures in the facility are limited natural brine inflow (Deal and Case, 1987; Deal and others, 1987; Deal and others, 1989) and localized spreading of water for dust control. However, the AIS is unusual because approximately 488,000 liters of brine were introduced into the AIS in an attempt to unclog the bit of the raisebore machine (Deal and others, 1989). The brine inundated the intersection of the S-90 and W-620 drifts, the station beneath the AIS, and the floor of the substation alcove. This area remained flooded for several months allowing infiltration into the fractures and the creation of locally saturated conditions.

Thorough characterization of the hydrologic conditions present in the area of the test was necessary before proceeding with the actual pump drawdown test. These conditions include: (1) the number and location of fractures; (2) saturation; (3) the occurrence of saturated muck on the drift floors; (4) fluctuating fluid levels in the AIS sump; and (5) water pressure and fluid levels existing in the holes prior to the test.

4.3.3.1 Fracturing and Saturation

Preliminary drilling confirmed that fractures saturated with brine occurred beneath much of the area around the AIS station and intersection of the S-90 and W-620 drifts. Fracture

observations were made visually and with a nail probe rod. At the time of this test, fracturing was clearly concentrated, almost exclusively, to the anhydrite (Marker Bed 139). Therefore the hydrogeologic unit being tested is fractured Marker Bed 139.

Holes OH-36, OH-37, OH-38, OH-41, OH-42, OH-43, and OH-44 filled quickly with water after the initial purging and recovered rapidly when pumped. These seven holes appeared to intersect a significant interconnected fracture system. Holes OH-35, OH-39, and OH-40 did not refill quickly after the initial purging. Inflow to OH-35 over the seven days following drilling and purging was minimal, with only 2.5 to 5 cm of water in the hole. At the same time OH-39 filled only 5 to 7.5 cm above the bottom of the hole. Hole OH-40 slowly filled to 2.8 m (within 23 cm of the top of the hole) during the seven days following the completion of drilling. These observations indicate that the area, including the AIS station, adjacent alcove, and S-90 drift, is not uniformly fractured.

Fluid levels in OH-36, OH-37, OH-41, OH-42, OH-43, and OH-44 were almost 1.8 m above Marker Bed 139 shortly after being drilled. Assuming that the permeability of the overlying unfractured halite is negligible in this short time frame, these data indicate that the marker bed was confined and under artesian head. Table 4-1 gives the measured water levels in ten observation holes prior to the pumping activities.

4.3.3.2 Local Saturation of Floor Muck

As part of the original construction of the access drifts, muck was spread on the alcove floor in order to construct a level surface. The muck later became saturated while the area was inundated with brine from the AIS and as a result of later watering of the alcove to assist in floor consolidation. It was necessary to dewater the overlying saturated muck to isolate it from the fractured hydrogeologic unit in the floor prior to the pumping tests.

During instrumentation of the testing area on April 27, 1989, several shallow trenches were excavated in order to bury pressure transducer cables. The shallow trenches quickly filled with brine during excavation. The entire floor of the transformer substation alcove was covered by saturated muck with a thickness up to 30 cm. Testing showed that the rapid fluid-level recovery in the observation holes located in the alcove (Figure 4-3) was produced by inflow from the muck. Preliminary testing of pumping rates for the planned hydrologic test indicated that the saturated muck could yield brine to the uncased, open observation holes at a rate equal to or greater than the full capacity of the pumping system. On May 2, 1989, a Bennett model air-driven piston pump was installed in OH-44, located at the back of the

transformer substation alcove. Pumping and observation of fluid levels in this, and surrounding holes, showed that the muck was saturated with brine in the area of the alcove and the drift intersection and that OH-44 was not connected to the fracture system beneath the intersection.

An attempt was made to dewater the saturated muck. Pumping was initiated on May 2, 1989, using the Bennett pump first in hole OH-44. The pump was then moved from OH-44 to OH-43, where the flow was adjusted to 88 liters per hour. The pump intake was set at approximately 0.6 m below the alcove floor and continued pumping overnight. By May 3, 1989, the fluid level had dropped to the pump intake, and inflow from the muck had decreased to a very small quantity. Observations indicated that 75 to 80 percent of the muck material had been dewatered in the test area. The pump was cycled on and off to continue dewatering the muck. In addition to the Bennett pump, a small hand pump was used in other surrounding holes to assist the dewatering efforts. All pumping activities stopped at the end of the day. The test area was allowed to recover.

The dewatering effort was reasonably successful; however, it did not remove all of the water from the muck. After the area recovered for 18 hours, the muck contained approximately 2.5 cm of saturated material above the contact with the underlying halite. This condition required that some of the holes be isolated from seepage from the muck. PVC casing was grouted in the upper 15 cm of these holes.

4.3.3.3 Fluid Levels in the Air Intake Shaft Sump

Construction design for the AIS includes the collection of groundwater seepage to the AIS in a water-collection ring within the shaft. The water is then piped to the AIS sump. (When construction of the shaft is completed, this seepage will be eliminated by grouting placed behind the shaft liner, as is the case now for the three completed shafts at the WIPP.) In practice, the water level in the sump is allowed to rise until it is almost full. The sump is then pumped down to accommodate additional storage needs. This cyclic process caused continual fluctuations of fluid levels in the AIS sump prior to conducting the hydrologic test. One objective of this test was to observe and quantify the relationship between the water level in the sump and the water level or hydrostatic pressure in macrofractures in Marker Bed 139 surrounding the sump. The bottom of the sump was very close to or at the upper surface of the marker bed, and the initial expectation was that fractures probably provided a hydrologic connection between the sump and unit being tested under the intersection.

The following investigation was performed to define this relationship. Holes OH-35, OH-36, OH-37, OH-42, and a small bolt hole directly beneath the AIS were instrumented with pressure transducers that constantly monitored fluid levels in the holes surrounding the AIS sump as the sump gradually filled. The sump was then rapidly pumped down more than 30 cm (4500 liters). The hydrographs of the resulting fluid pressures in holes OH-36, OH-37 and OH-42 are shown in Figure 4-4.

Fluid levels in these surrounding holes were unresponsive to either the slow rise or the rapid decline in fluid level in the sump. These observations suggest that there is not a significant or open connection between the AIS sump and the fractured part of Marker Bed 139. Apparently the AIS sump did not act as a constant head-type boundary or provide an immediate source of recharge to the zone of macrofracturing. However, longer time frames or higher fluid levels in the AIS sump might provide recharge to the fractured marker bed.

4.3.3.4 Background Water Pressure and Water Level Data

Background water pressure and water level data were collected to provide some definition of long-term trends, changes regarding test parameters, and comparison with the hydrologic test results. Background data collection began May 1, 1989, in holes OH-35, OH-36, OH-37, OH-42, and in the bolt hole beneath the AIS. Holes OH-41 and OH-43 began providing data on the second day while OH-44 started producing data on the third day.

The fluid pressures in OH-36 (pumped hole), OH-37, OH-41, and OH-42 from the initial instrumentation through the completion of the pumping drawdown test are shown on Figure 4-5. The pretest fluid levels showed a slight decline in level with time. On May 4, 1989, at approximately 12 p.m., PVC casing was grouted to the upper 15 cm of four holes to stop the inflow of brine from the partially saturated muck. The holes were pumped down at least 15 cm and the PVC casing was grouted in place. Review of Figure 4-5 shows that these activities influenced the fluid levels and the downhole pressures as monitored by the transducers in several holes. The transducers in OH-36, OH-37, OH-43, and OH-44 were removed during installation of the PVC pipe. After installation of the pipe, the transducers were reinstalled at somewhat different depths than their original placement.

In summary, background water-level data showed that the fluid pressures in fractures within Marker Bed 139 were independent of the water level in the AIS sump. Seepage from the

FIGURE 4-4 FLUID PRESSURES IN HOLES OH-36, OH-37, AND OH-42 AFTER REMOVAL OF 4500 LITERS OF BRINE FROM THE AIS SUMP

FIGURE 4.5 HYDROGRAPH OF HOLES OH-36, OH-37, OH-41, AND OH-42, THROUGH THE END OF THE PUMPING TEST

surrounding saturated muck influenced the pretest fluid levels, introducing some degree of uncertainty to pump test data and the resulting interpretation. The uncertainty was minimized by installing surface casing.

4.3.4 Preliminary Step Drawdown Testing

The Bennett pump was installed in hole OH-41 at the front of the alcove on May 4, 1989. This hole was pumped at several flow rates, ranging from 19 to 76 liters per hour, to establish an appropriate flow rate for the pumping drawdown test. After nine minutes of pumping, the hole completely dewatered. The water level recovered only 0.6 m within the next hour. The pump was moved to OH-36 in the center of the S-90 drift. Step drawdown testing was conducted using flow rates between 11 and 38 liters per hour. These results indicated that hole OH-36 would yield water at a greater rate than hole OH-41. The optimum flow rate was determined to be approximately 34 liters per hour. Calculations, based on the short duration step drawdown test, indicated that the pumped hole (OH-36) would not be dewatered within 24 hours at a flow rate of 34 liters per hour. Preliminary testing was concluded on May 4, 1989, and the test area recovered overnight for the start of the main pumping drawdown test scheduled for the following day.

4.4 FINAL PUMP TEST

A pumping drawdown-type hydrologic test was conducted in Marker Bed 139 at the intersection of the S-90 and W-620 drifts. The test started at 10:10 a.m. on May 5, 1989, with the pump installed in hole OH-36. Figure 4-3 shows the test-site configuration, the holes that were monitored with pressure transducers, the pumping hole, and the holes containing water level probes. For the purpose of the test, the pressure transducer in hole OH-35 was removed and placed in hole OH-38. The higher fluid level in OH-38 would produce more useful drawdown data.

4.4.1 Test Performance and Results

Problems with the pumping rate arose during the startup phase of the pumping test. The initial plan called for a flow rate of 34 liters per hour. This relatively low flow rate required very careful adjustment of the air pressure and delicate adjustments to the control valve on the discharge line from the Bennett pump. The first measurement indicated a flow rate of about 19 liters per hour that declined to 11 liters per hour in five minutes. The pressure and valve settings were adjusted until a flow rate of approximately 34 liters per hour was reached. The adjustment period was continuous for the first 75 minutes of the test. This adjustment period

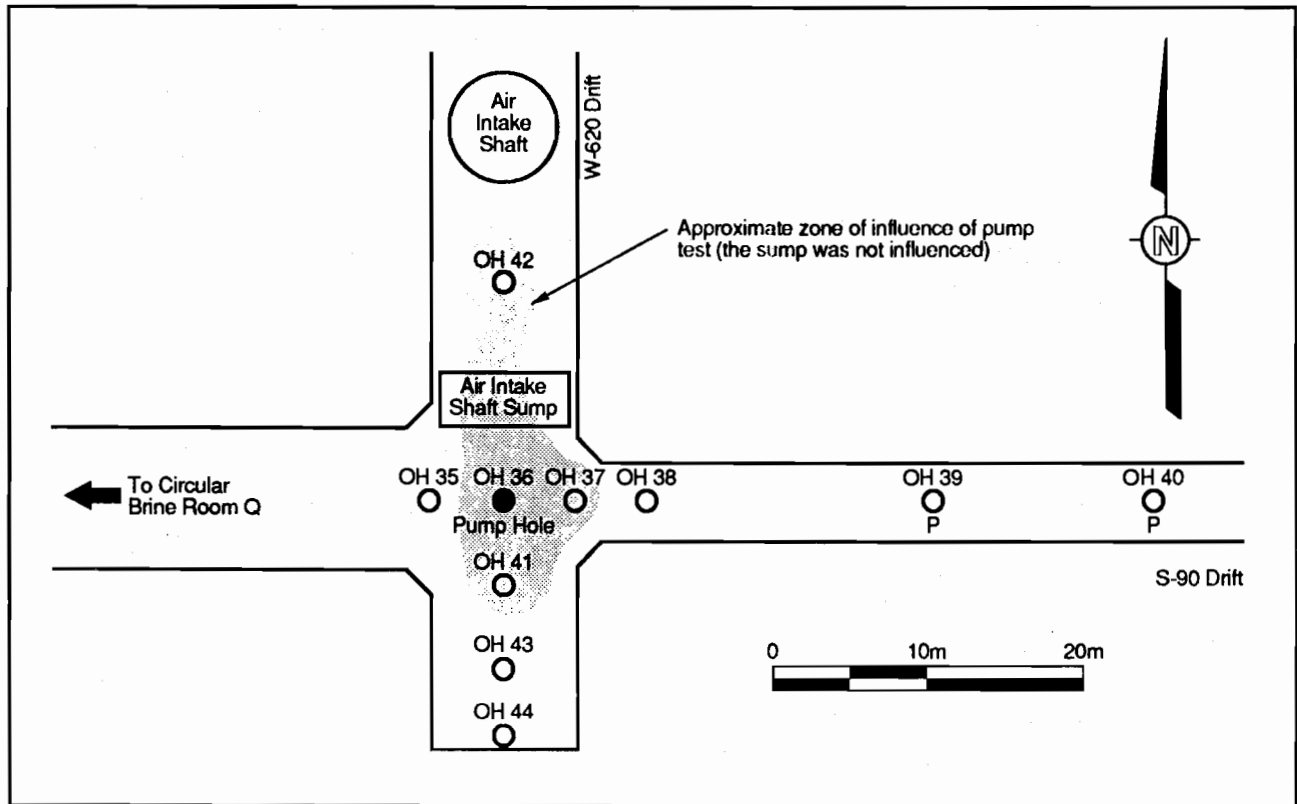

caused the early test results to be poor, and did not allow for a constant steady flow rate and drawdown to occur until almost 120 minutes of early test time had elapsed.

After a steady discharge rate was established, down-hole fluid pressures were monitored on a one-minute interval for 80 minutes. The logging interval was increased to 15 minutes for the remainder of the test. Pumping in hole OH-36 continued for 26 hours. In order to achieve a continuous removal of water from the pump hole it was necessary to maintain a water level above the pump intake. The ending fluid level was approximately 15 cm above the pump intake.

All pumping and pressure-monitoring equipment functioned well throughout the test with the exception of the pressure transducer installed in the bolt hole beneath the AIS. This transducer malfunctioned, reading negative pressure values on May 4, 1989. A visual inspection of the area beneath the AIS revealed that the fluid level in the bolt hole was lower than it had been when the transducer was installed. However, the fluid level appeared to be sufficiently high for positive pressure readings. From that point on, no reliable pressure data was collected from that monitoring station.

The drawdown of fluid level in Marker Bed 139 was detected in some of the observation holes monitored during the pumping test. Only OH-36 (pump hole), OH-37, OH-41, and OH-42 showed measurable drawdown response to pumping (Figure 4-5). Fluid levels in remaining holes showed no drawdown response. These results indicate that there are separate, hydrologically unconnected, saturated fracture systems within Marker Bed 139. OH-38 is 8.3 m from the pumped hole. This hole filled rapidly with inflow from fractures after drilling and initial evacuation, but did not show any response to pumping. Although OH-40 was full of brine at the start of the test, it showed no response. OH-39, located on the east side of the S-90 drift, showed no response to the test even though it contained a few centimeters of brine at the start of the test, with a surface level far below that in the holes at the intersection. Hole OH-37, 4.1 m west of OH-38, showed rapid and immediate response to pumping. These observations indicate that the intersection of the S-90 and W-620 drifts and along the W-620 drift toward the AIS has more enhanced fracturing than does the S-90 drift (see Figure 4-6).

The testing results also suggest that the fractures in Marker Bed 139 at the drift intersection are fairly well connected. This confirms the pre-test expectations of the distribution and development of macrofractures (Section 4.3.1).

**FIGURE 4-6
OBSERVATION HOLE RESPONSE TO PUMP TEST**

4.4.2 Pumping Test Analysis

The Jacobs, Theis, and Thiem methods were used to determine transmissivity and storage coefficients in the holes that responded to pumping. Figures 4-7 through 4-13 show semi-log plots of drawdown vs. time for all wells instrumented with transducers. The drawdown curves for holes OH-36, OH-37, OH-41 and OH-42 show a linear plot of drawdown vs. time. This allowed the data to be analyzed with the standard Theis nonequilibrium formula as modified by Jacobs (Lohman, 1972). The calculated transmissivity for all observation holes, including the pumping hole, are 0.11 to 0.18 m²/day. Storage coefficients calculated for holes OH-37, OH-41, and OH-42 ranged from 3.3×10^{-4} to 7.3×10^{-4} . These values for transmissivity and storage coefficient are very consistent from hole to hole. This indicates that the area affected by the test has a fairly uniform fracture system, resulting in uniform hydrologic characteristics. Figure 4-14 shows a semi-log distance vs. drawdown plot. This figure shows the drawdown in holes OH-37, OH-41, and OH-42 at 1,000 minutes of pumping time. The transmissivity and storage coefficient, calculated by the Thiem method of distance drawdown were 0.16 m²/day and 3.7×10^{-4} , respectively. The results of the Thiem analysis (Lohman, 1972) are very consistent with those calculated using the nonequilibrium equation.

The fluid level drawdown data for observation holes OH-37 and OH-41 were analyzed using the Theis-type curve technique (Lohman, 1972). Drawdown values were plotted versus r^2/t (distance from observation hole to pumped hole/time since pumping began) using log-log axes. This analysis shows that the marker bed acts as a porous medium. The log-log data curves fit the established type curves of Theis fairly well. The transmissivity and storage coefficients calculated by this method agreed well with values calculated using the other analytical techniques. Calculated values for the transmissivity and storage coefficient for hole OH-37 are 0.10 m²/day and 7.64×10^{-4} , and for OH-41 are 0.10 m²/day and 1.04×10^{-3} , respectively. It is noted that these methods require the assumption that the aquifer is infinite. With the exception of OH-42 (discussed later), a boundary was not observed. The testing provided enough data to curve-fit for more than one log cycle, indicating that the assumption of an infinite aquifer is not seriously violated.

A much more rigorous analysis of the test data should be performed using techniques such as those discussed in Beauheim (1987). Defining complete hydrologic characteristics, such as double porosity vs. single porosity response, or the orientation and nature of single or multiple fractures will require more detailed hydrologic testing and analysis outside the scope of this preliminary test.

FIGURE 4-13. SEMI-LOG PLOT OF DRAWDOWN VS. TIME FOR OBSERVATION HOLE OH-44

FIGURE 4-14. SEMI-LOG PLOT OF DRAWDOWN VS. DISTANCE FROM PUMPED HOLE

The results of this test showed areas where the marker bed contains both macrofractures and brine adequate for successful hydrologic testing. The effects of local boundary conditions remain unresolved by the test. Only OH-42, located north of the AIS sump, showed the influence of a nearby no-flow or low permeability boundary. Figure 4-10 shows a prominent change in slope of the drawdown vs. log time plot. This change in slope indicates that the cone of depression encountered a low permeability area at approximately 800 minutes into the test. A similar boundary is not observed in drawdown plots of the other observation holes. Quantitative evaluation of boundary conditions, boundary locations, and the general distribution of high and low permeability areas will require additional testing and a larger network of observation holes. However, the boundary conditions seen in hole OH-42 indicate that pump testing in saturated areas can provide important definition of the distribution and hydrologic relationship of local areas which exhibit highly variable permeability.

Upon completion of the pumping-drawdown test, fluid levels in all observation holes were monitored for several weeks. After two weeks, fluid levels remained below the pretest level. These observations indicate that the fracture system involved in the test is limited in area and has very limited, if any, connection to other saturated fracture systems. It appears that the pumping test partially dewatered a local region of the marker bed. This type of testing can provide considerable information on the distribution and interconnection of fractures beneath the floor of the WIPP excavations.

4.5 SUMMARY OF TEST RESULTS

This pumping drawdown test provided valuable data on the hydrogeologic characteristics in the area tested. The limited scope of this program represents a preliminary attempt to characterize hydrological conditions in the fractures beneath the floor of the WIPP excavations. The test showed that hydrologic parameters can be defined, and the relationship of fractures or fracture systems can be determined with standard hydrologic testing techniques in areas where the marker bed is saturated. Transmissivities of 0.1 to 0.2 m²/day, as determined from this test, are several orders of magnitude higher than those measured elsewhere in Marker Bed 139. These data show that fractured zones beneath the WIPP excavations can be highly permeable. Numerous tests would be required to quantify the distribution of permeability, storativity, and fracture geometry in any specific area.

The following is recommended for future testing:

- A preadjusted low pumping rate
- The area to be pumped should be unstressed for several days
- All holes should be cased and grouted into the undisturbed halite.

L1S29	L1	A	N1524	W226	400	10	3.7	D	90	B, H	Monitored as part of BSEP from 8/85 to 6/89.
L1S30	L1	A	N1524	W228	400	10	3.7	D	90	B, H	Monitored as part of BSEP from 8/85 to 6/89.
L1S31	L1	A	N1524	W235	400	10	3.6	D	90	B, H	Monitored as part of BSEP from 8/85 to 6/89.
L1S32	L1	A	N1524	W237	400	10	3.6	D	90	B, H	Monitored as part of BSEP from 8/85 to 6/89.
L1S33	L1	A	N1524	W239	400	10	3.6	D	90	B, H	Monitored as part of BSEP from 8/85 to 6/89.
L1S34	L1	A	N1524	W241	400	10	3.7	D	90	B, H	Monitored as part of BSEP from 8/85 to 6/89.
L1S35	L1	A	N1524	W243	400	10	3.8	D	90	B, H	Monitored as part of BSEP from 8/85 to 6/89.
L1S36	L1	A	N1524	W245	400	10	3.7	D	90	B, H	Monitored as part of BSEP from 8/85 to 6/89.
L1X00	L1	A	N1538.5	W225	400	10	3.8	D	90	B, H	Drillers found water in hole at 3 m, 5/13/84. Monitored as part of the BSEP from 10/84 to 4/89.
L2C03	L2	A	N1510	W365	400	41	3.7	D	90	B, H	Drilled 4/85 overcoring and destroying L2C25. Brine and gas enters hole quickly through open fractures. Monitored intermittently as part of BSEP from 12/85 through 12/86.
L2C25	L1	A	N1510	W365	400	12.7	3.5	D	90	B, H	L2C25 is a 12.7 cm overcore of a previously grouted SNL test hole. The overcore was drilled 3/85 and air and brine was blown through fractures into hole L2C29, 1.2 m to the north. In 4/85, a 40 cm overcore was made destroying this hole. The larger hole is designated L2C03.
MIIT2	J	S	N1088.03	W377.02	393.44	8.3	0.9	D	90	B, D, G	Brine since drilled, monitored from 10/84 to 4/85.
MIIT4	J	S	N1086.05	W377.13	393.44	8.3	1.0	D	90	B, D, G	Brine since drilled, monitored from 10/84 to 4/85.

APPENDIX B
GRAPHS OF BRINE ACCUMULATION DATA

APPENDIX B

GRAPHS OF BRINE ACCUMULATION DATA

This appendix contains graphs of data presented in Appendix A for selected locations. As described in Deal and Case (1987), much of the variability in the quantity of brine collected resulted from limitations of the collecting techniques rather than variations in the actual inflow of brine from bedrock at the collecting locations. As a result, plotting of the inflow data from the data tables (Appendix A) results in an irregular plot that implies variations in inflow that, in fact, do not exist. The graphed data included in this report were processed and plotted by a standard software program (STSC Statgraphics)¹ on an IBM XT microcomputer, using an 11-point moving average to smooth the curve, unless otherwise stated. The smoothed data reflect trends in the body of the curve that are representative of the brine seepage rates while still showing variations that are probably the result of collecting techniques.

At the beginning and end of each curve the smoothing program projects the calculated trend. As a result, initial and ending real values, usually zero, and maximum inflow values within the first few data points, tend to be distorted by the smoothing program. In order to correct the distortion caused by the smoothing program, the smoothed data are replaced by the actual data for the first and last few data points prior to plotting. Additional discussion of the collection and data handling is provided in Deal and Case (1987).

APPENDIX C

ANALYTICAL RESULTS FOR BRINE SAMPLES

TABLE C-1 KEY, ANALYTICAL RESULTS

LAB	UNC = United Nuclear Corporation IT = International Technology
SG	Specific Gravity
TDS	Total Dissolved Solids
EXT ALK*	Extended Alkalinity; * Reported as equivalent HCO_3^- solutions titrated to end point pH of 2.5
TIC**	Total Inorganic Carbon; ** Reported as equivalent HCO_3^-
TOC**	Total Organic Carbon; ** Reported as equivalent HCO_3^-
Br	Bromide
Cl	Chloride
F	Fluoride
I	Iodide
NO_3	Nitrate
NH_4	Ammonium
PO_4	Phosphate
SO_4	Sulfate
