
**Title 40 CFR Part 191
Subparts B and C
Compliance Recertification
Application
for the
Waste Isolation Pilot Plant**

**Appendix SOTERM-2009
Actinide Chemistry Source Term**

**United States Department of Energy
Waste Isolation Pilot Plant**

**Carlsbad Field Office
Carlsbad, New Mexico**

Appendix SOTERM-2009
Actinide Chemistry Source Term

Table of Contents

SOTERM-1.0 Introduction	SOTERM-1
SOTERM-2.0 Expected WIPP Repository Conditions, Chemistry, and Processes	SOTERM-3
SOTERM-2.1 Ambient Geochemical Conditions	SOTERM-3
SOTERM-2.2 Repository Conditions	SOTERM-3
SOTERM-2.2.1 Repository Pressure	SOTERM-5
SOTERM-2.2.2 Repository Temperature	SOTERM-5
SOTERM-2.2.3 Water Content and Relative Humidity	SOTERM-5
SOTERM-2.2.4 Minimum Repository Brine Volume	SOTERM-6
SOTERM-2.2.5 DRZ	SOTERM-7
SOTERM-2.3 Repository Chemistry	SOTERM-7
SOTERM-2.3.1 WIPP Brine	SOTERM-7
SOTERM-2.3.2 Brine pH and pH Buffering	SOTERM-9
SOTERM-2.3.3 Selected MgO Chemistry and Reactions	SOTERM-13
SOTERM-2.3.4 Iron Chemistry and Corrosion	SOTERM-14
SOTERM-2.3.5 Chemistry of Lead in the WIPP	SOTERM-16
SOTERM-2.3.6 Organic Chelating Agents	SOTERM-17
SOTERM-2.3.7 CPR in WIPP Waste	SOTERM-19
SOTERM-2.4 Important Postemplacement Processes	SOTERM-19
SOTERM-2.4.1 Microbial Effects in the WIPP	SOTERM-19
SOTERM-2.4.2 Radiolysis Effects in the WIPP	SOTERM-23
SOTERM-2.5 Changes in WIPP Conditions since the CRA-2004 and the CRA- 2004 PABC	SOTERM-27
SOTERM-3.0 WIPP-Relevant Actinide Chemistry	SOTERM-29
SOTERM-3.1 Actinide Inventory in the WIPP	SOTERM-30
SOTERM-3.2 Thorium Chemistry	SOTERM-33
SOTERM-3.2.1 Thorium Environmental Chemistry	SOTERM-33
SOTERM-3.2.2 WIPP-Specific Results since the CRA-2004 and the CRA- 2004 PABC	SOTERM-35
SOTERM-3.3 Uranium Chemistry	SOTERM-37
SOTERM-3.3.1 Uranium Environmental Chemistry	SOTERM-38
SOTERM-3.3.2 WIPP-Specific Results since the CRA-2004 and the CRA- 2004 PABC	SOTERM-45
SOTERM-3.4 Neptunium Chemistry	SOTERM-47
SOTERM-3.4.1 Neptunium Environmental Chemistry	SOTERM-47
SOTERM-3.4.2 WIPP-Specific Results since the CRA-2004 and the CRA- 2004 PABC	SOTERM-48
SOTERM-3.5 Plutonium Chemistry	SOTERM-48
SOTERM-3.5.1 Plutonium Environmental Chemistry	SOTERM-49
SOTERM-3.5.2 WIPP-Specific Results since the CRA-2004 and the CRA- 2004 PABC	SOTERM-52
SOTERM-3.6 Americium and Curium Chemistry	SOTERM-54
SOTERM-3.6.1 Americium and Curium Environmental Chemistry	SOTERM-55
SOTERM-3.6.2 WIPP-Specific Results since the CRA-2004 and the CRA- 2004 PABC	SOTERM-58
SOTERM-3.7 Complexation of Actinides by WIPP Organic Chelating Agents	SOTERM-60

SOTERM-3.8 Actinide Colloids.....	SOTERM-60
SOTERM-3.8.1 Actinide Colloids in the Environment.....	SOTERM-61
SOTERM-3.8.2 WIPP-Specific Results since the CRA-2004 PABC	SOTERM-63
SOTERM-3.9 Changes in Actinide Speciation Information since the CRA-2004 and the CRA-2004 PABC.....	SOTERM-63
SOTERM-4.0 Calculation of the WIPP Actinide Source Term	SOTERM-66
SOTERM-4.1 Overview of WIPP Approach to Calculate Actinide Solubilities	SOTERM-67
SOTERM-4.2 Use of Oxidation-State-Invariant Analogs.....	SOTERM-67
SOTERM-4.3 Actinide Inventory and Oxidation State Distribution in the WIPP ..	SOTERM-69
SOTERM-4.4 Actinide Speciation Reactions Used in the FMT Model.....	SOTERM-70
SOTERM-4.4.1 The III Actinides: Pu(III), Am(III), Cm(III)	SOTERM-71
SOTERM-4.4.2 The IV Actinides: Th(IV), U(IV), Pu(IV), Np(IV)	SOTERM-71
SOTERM-4.4.3 The V Actinides: Np(V).....	SOTERM-74
SOTERM-4.4.4 The VI Actinides: U(VI)	SOTERM-75
SOTERM-4.5 Calculations of Actinide Solubility Using the FMT Computer Code	SOTERM-76
SOTERM-4.5.1 Pitzer Approach for High-Ionic-Strength Brines	SOTERM-76
SOTERM-4.5.2 Calculated Actinide Solubilities.....	SOTERM-77
SOTERM-4.6 Calculation of the Effects of Organic Ligands on Actinide Solubility.....	SOTERM-79
SOTERM-4.7 Calculation of Colloidal Contribution to Actinide Solution Concentrations	SOTERM-80
SOTERM-5.0 Use of the Actinide Source Term in PA.....	SOTERM-83
SOTERM-5.1 Simplifications.....	SOTERM-83
SOTERM-5.1.1 Elements and Isotopes Modeled.....	SOTERM-83
SOTERM-5.1.2 Use of Brine End Members	SOTERM-84
SOTERM-5.1.3 Sampling of Uncertain Parameters.....	SOTERM-85
SOTERM-5.1.4 Combining the Transport of Dissolved and Colloidal Species in the Salado	SOTERM-88
SOTERM-5.2 Construction of the Source Term	SOTERM-88
SOTERM-5.3 Example Calculation of Actinide Solubility	SOTERM-91
SOTERM-5.4 Calculated Dissolved, Colloidal, and Total Actinide Solubilities....	SOTERM-91
SOTERM-6.0 References	SOTERM-94

List of Figures

Figure SOTERM-1. Molal H ⁺ Concentration Measured as a Function of Time During the Solubility Experiments in 2.67 and 5.15 m MgCl ₂ Solution	SOTERM-12
Figure SOTERM-2. Expected Dominant Actinide Oxidation States as a Function of the Standard Reduction Potential at pH = 7 in Water That is in Equilibrium With Atmospheric CO ₂	SOTERM-23
Figure SOTERM-3. NaCl Brine Radiolysis Species and Suggested Mechanism of Production.....	SOTERM-25
Figure SOTERM-4. Radiolytic Formation of Hypochlorite Ion in Solutions of Various NaCl Concentrations at a Constant Alpha Activity	

	of 37 GBq/L at pH~12 (Based on Data in Kelm, Pashalidis, and Kim 1999)	SOTERM-25
Figure SOTERM-5.	Solubility of Amorphous Th(IV) Oxyhydroxide as a Function of Carbonate Concentration in 5 M for pH = 2–8 (A) and pH = 8–13.5 (B)	SOTERM-36
Figure SOTERM-6.	Solubility of Th(OH) ₄ (am) Determined from Undersaturation in 0.5 NaCl, 5.0 M NaCl, and 2.5 M MgCl ₂	SOTERM-37
Figure SOTERM-7.	Reduction Potential Diagram for U at pH = 0, 8, and 14 (Based on Data in Morss, Edelstein, and Fuger 2006)	SOTERM-38
Figure SOTERM-8.	Predominance Diagrams for U as a Function of Log P _{O₂} and pH: (A) Predominant Solid Phases; (B) Predominant Aqueous Species	SOTERM-41
Figure SOTERM-9.	Solubility of UO ₂ (s) as a Function of pH at 20–25 °C (68–77 °F) in 1M NaCl (based on Neck and Kim 2001)	SOTERM-42
Figure SOTERM-10.	U(VI) Solubility in Carbonate-Free Brine Versus pC _{H+} for GWB (Top Curve) and ERDA-6 (Bottom Curve)	SOTERM-45
Figure SOTERM-11.	Speciation Diagram for Plutonium in Carbonated Low-Ionic-Strength Groundwater (Based on Data Presented in Runde et al. 2002)	SOTERM-50
Figure SOTERM-12.	Comparison of the Reactivity of Iron Powder and Iron Coupon Towards Pu(VI)	SOTERM-53
Figure SOTERM-13.	The Concentration of Pu as a Function of Time in the Presence of Iron Powder, Iron Coupon, Ferric Oxide, and Magnetite (Mixed Iron Oxide) (Reed et al. 2009)	SOTERM-54
Figure SOTERM-14.	Redox Potential for Some Am Redox Couples (Silva et al. 1995, p. 74)	SOTERM-55
Figure SOTERM-15.	Composite of Nd Solubility Trends Under All Conditions Investigated (Borkowski et al. 2008)	SOTERM-59
Figure SOTERM-16.	Predominant Am Species as a Function of pH and E _h Based on the Speciation Reactions (SOTERM.34) to (SOTERM.47) (Richmann 2008)	SOTERM-72
Figure SOTERM-17.	Predominant Species of Th as a Function of pH and Redox Conditions (Richmann 2008)	SOTERM-73
Figure SOTERM-18.	Predominant Species Diagram for Np as a Function of pH and E _h Based on the Np Speciation Data Reactions (SOTERM.60) to (SOTERM.70) (Richmann 2008)	SOTERM-75
Figure SOTERM-19.	Frequency Distribution of the Deviation of Experimental log Solubility from Model-Predicted Value for all An(III) Comparisons	SOTERM-86
Figure SOTERM-20.	Frequency Distribution of the Deviation of Experimental log Solubility from Model-Predicted Value for all An(IV) Comparisons	SOTERM-87
Figure SOTERM-21.	Cumulative Distribution Function for the Humic-Acid Proportionality Constant	SOTERM-88

List of Tables

Table SOTERM-1.	Summary of Current WIPP Chemistry Model Assumptions (Leigh et al. 2005).....	SOTERM-4
Table SOTERM-2.	Compositions of GWB and ERDA-6 Prior To and After Equilibration with MgO (Brush et al. 2006).....	SOTERM-8
Table SOTERM-3.	Redox Half-Reaction Potentials for Key Fe, Pb, Pu, and U Reactions at 25 °C and I<1 (Morss, Edelstein, and Fuger 2006, Chapter 23).....	SOTERM-15
Table SOTERM-4.	Concentrations of Organic Ligands in WIPP Brine Calculated for Use in the CRA-2004 PABC (Brush and Xiong 2005a)	SOTERM-18
Table SOTERM-5.	Apparent Stability Constants for Organic Ligands with Selected Metals (National Institute of Standards and Technology 2004).....	SOTERM-18
Table SOTERM-6.	Overview of the WIPP PA View/Role and Relevant Environmental Chemistry of the Key Actinide Species in the WIPP (References for Each Actinide are Provided in the Following Sections)	SOTERM-31
Table SOTERM-7.	WIPP Radionuclide Inventory (U.S. Department of Energy 2006) Decay-Corrected to 2002.....	SOTERM-32
Table SOTERM-8.	Total Amount (in Kilograms) of Key Waste Package Components and Actinides Present in WIPP Panels 1 and 2 (Based on Data in Lucchini et al. 2007)	SOTERM-33
Table SOTERM-9.	Thermodynamic Stability Constants for Key Th Hydrolytic Species	SOTERM-34
Table SOTERM-10.	Complexation Constants for Binary U(VI) Carbonate Complexes at I = 0 M and 25 °C (Guillaumont et al. 2003)....	SOTERM-43
Table SOTERM-11.	Solubility of U(VI) in High-Ionic-Strength Media.....	SOTERM-46
Table SOTERM-12.	Hydrolysis Constants of Am(III) (in Logarithmic Units) Corresponding to Equation (SOTERM.30)	SOTERM-57
Table SOTERM-13.	Apparent Stability Constants for the Complexation of Organic Ligands with Actinides in NaCl Media (Choppin et al. 1999)	SOTERM-60
Table SOTERM-14.	List of Documents and Reports that Support the CRA-2004 PABC	SOTERM-66
Table SOTERM-15.	WIPP Radionuclide Inventory at Closure (in 2033) Used in PABC-2005 Calculations (Leigh, Trone, and Fox 2005).....	SOTERM-69
Table SOTERM-16.	Oxidation States of the Actinides in the WIPP as Used in the CRA-2004 PABC.....	SOTERM-70
Table SOTERM-17.	Solubilities of the Oxidation-State Analogs (M) with MgO Backfill Calculated for the CRA-2004 PABC (Brush 2005)...	SOTERM-78
Table SOTERM-18.	Historical Actinide Solubilities (M) Calculated (III, IV, and V) or Estimated (VI) for the CRA-2004 PA, the CCA PAVT and the CCA PA (U.S. Department of Energy 2004)...	SOTERM-78
Table SOTERM-19.	Comparison of Actinide Solubility Calculations With and Without Organics.....	SOTERM-80

Table SOTERM-20.	Classification of Four Colloid Types Considered by WIPP PA	SOTERM-80
Table SOTERM-21.	Material and Property Names for Colloidal Parameters	SOTERM-81
Table SOTERM-22.	Colloid Concentration Factors (The CRA-2004, Appendix PA, Attachment SOTERM)	SOTERM-82
Table SOTERM-23.	Actinide Concentration or Maximum Concentration Due to Colloidal Enhanced Solution Concentrations (Garner and Leigh 2005).....	SOTERM-82
Table SOTERM-24.	WIPP PA Modeling Scenarios for the CRA-2004 PABC (Garner and Leigh 2005; Leigh et al. 2005)	SOTERM-84
Table SOTERM-25.	Concentrations (M) of Dissolved, Colloidal, and Total Mobile Actinides Obtained Using Median Parameter Values for the CCA PAVT and CRA-2004 PABC ^a	SOTERM-92

Acronyms and Abbreviations

%	percent
α	alpha particle
a_c	activity of a chemical species
μm	micrometer, micron
ACP	LANL-CO Actinide Chemistry Project
am	amorphous
AP	Analysis Plan
aq	aqueous
ASTP	Actinide Source Term Program
atm	atmosphere
β	(apparent) stability constant, or beta particle
Bq	becquerel
BRAGFLO	Brine and Gas Flow code
CAPHUM	maximum (cap) concentration of actinide associated with mobile humic colloids
CAPMIC	maximum concentrations of actinides that could be associated with microbes
CCA	Compliance Certification Application
Ci	Curie
cm^{-1}	per centimeter
CN	coordination number
coll	colloid
conc	concentration
CONCINT	concentration of actinide associated with mobile actinide intrinsic colloids
CONCMIN	concentration of actinide associated with mobile mineral fragment colloids
CPR	cellulosic, plastic, and rubber
C_{Pu}	maximum concentration of all combined isotopes of Pu
cr	crystalline phase
CRA	Compliance Recertification Application
DBR	direct brine release
D-H	Debye-Hückel theory
DOE	U.S. Department of Energy
DRZ	disturbed rock zone

EDTA	ethylenediaminetetraacetic acid
EPA	U.S. Environmental Protection Agency
EQ3/6	software package for geochemical modeling of aqueous systems
eV	electron volt
EXAFS	Extended X-Ray Absorption Fine Structure
f_{CO_2}	fugacity of carbon dioxide
FMT	Fracture-Matrix Transport
ft	feet
γ	gamma radiation or activity coefficient
g	gaseous, or gram
g/mL	gram per milliliter
GBq	giga becquerel
GWB	Generic Weep Brine, a synthetic brine representative of fluids in Salado brine reservoirs
h	hours
I	ionic strength
K	degree Kelvin or stability constant
kg	kilogram
K_{sp}	solubility product
L	liter
LANL	Los Alamos National Laboratory
LET	Linear Energy Transfer
log	logarithm
\log_{10}	logarithm base 10
m	meter, molal
M	mole per liter
m^2	square meter
m^3	cubic meter
mg/L	milligram per liter
mL	milliliter
mM	millimole per liter
mol	mole
molec	molecule

MPa	megapascal
N	degree of polymerization number
N _A	Avogadro's number
NIST	National Institute of Standards and Technology
nm	nanometer
NUTS	Nuclide Transport System code
orgs	organics
OXSTAT	oxidation state parameter
PA	Performance Assessment
PABC	Performance Assessment Baseline Calculation
PAVT	Performance Assessment Verification Test
pC _{H⁺} or pCH	Negative logarithm of H ⁺ concentration in moles per liter
pCO ₂	Partial pressure of carbon dioxide
pH	negative logarithm of H ⁺ activity
pH _{obs}	negative logarithm of H ⁺ activity measured
PHUMCIM	Proportionality constant for concentration of actinides associated with mobile humic colloids, in Castile brine
PHUMOX _n	Proportionality constant for humic colloids and actinides in the +n oxidation state
PHUMSIM	Proportionality constant for concentration of actinides associated with mobile humic colloids, in Salado brine
pK _a	negative logarithm of the dissociation constant of an acid
pm	picometer
pmH	negative logarithm of H ⁺ concentration in molal
P _{O₂}	partial pressure of molecular oxygen
PROPMIC	proportionality constant describing the amount of actinide element bound to mobile microbes
RH	relative humidity
s	solid or second
SECOTP2D	computer program that simulates single or multiple component radionuclide transport in fractures or granular aquifers
SEM	scanning electron microscope
SNL	Sandia National Laboratories
SOTERM	WIPP Actinide Source Term
SPC	Salado Primary Constituents

t _½	half-life
TDS	total dissolved solid
TRU	transuranic
TWBIR	Transuranic Waste Baseline Inventory Report
V	volt, or vanadium
w	with
WIPP	Waste Isolation Pilot Plant
WWIS	WIPP Waste Information System
XANES	X-Ray Absorption Near Edge Structure
XRD	X-Ray Diffraction
yr	year

Elements and Chemical Compounds

Am	Americium
Am(III)	Americium in the +3 oxidation state
Am(IV)	Americium in the +4 oxidation state
Am(V)	Americium in the +5 oxidation state
Am(VI)	Americium in the +6 oxidation state
Am ²⁺	Americium cation - Aqueous form of the americium in the +2 oxidation state that only exists as a transient
Am ³⁺	Americium cation - Aqueous form of the americium in the +3 oxidation state
Am ⁴⁺	Americium cation - Aqueous form of the americium in the +4 oxidation state
Am(CO ₃) _n ⁽³⁻²ⁿ⁾	Americium (III) carbonate complex with n=1, 2, or 3
AmCO ₃ OH	Americium (III) carbonato hydroxide
AmO ₂ ⁺	Americium oxo-cation – Aqueous form of the americium in the +5 oxidation state
AmO ₂ ²⁺	Americium oxo-cation – Aqueous form of the americium in the +6 oxidation state
AmO ₂ OH	Americium (V) oxide hydroxide
AmOH ²⁺	Americium (III) hydroxide cation – (1:1) complex
Am(OH) ₂ ⁺	Americium (III) hydroxide cation – (1:2) complex
Am(OH) ₃	Americium hydroxide
AmPO ₄	Americium (III) phosphate
Am(SO ₄) _n ⁽³⁻²ⁿ⁾	Americium (III) sulfate complex with n = 1 or 2
[An] _p	Concentration of an adsorbed actinide element (mol/particle)
An	Actinide
An(III)	General actinide in the +3 oxidation state
An(IV)	General actinide in the +4 oxidation state
An(V)	General actinide in the +5 oxidation state
An(VI)	General actinide in the +6 oxidation state
An ³⁺	Aqueous form of the actinide in the +3 oxidation state
An ⁴⁺	Aqueous form of the actinide in the +4 oxidation state
An ⁿ⁺	Aqueous form of the actinide in the +n oxidation state
An ₂ (CO ₃) ₃	Actinide (III) carbonate – (2:3) complex

$An_2(CO_3)_2^{2+}$	Actinide (III) carbonate ion – (2:2) complex
$AnB_4O_7^+$	Actinide (III) tetraborate ion – (1:1) complex
$AnCl^{2+}$	Actinide (III) chloride ion – (1:1) complex
$An(CO_3)^+$	Actinide (III) carbonate ion – (1:1) complex
$An(CO_3)_2^-$	Actinide (III) carbonate ion – (1:2) complex
$An(CO_3)_3^{3-}$	Actinide (III) carbonate ion – (1:3) complex
$AnCO_3OH$	Actinide (III) carbonate hydroxide
$AnL^{(n+m)}$	Complex of an actinide with a charge n and an organic ligand L with a charge m
$An(V)O_2^+$ or AnO_2^+	Aqueous form of the actinide in the +5 oxidation state
$An(VI)O_2^{2+}$ or AnO_2^{2+}	Aqueous form of the actinide in the +6 oxidation state
$AnOH^{2+}$	Actinide (III) hydroxide cation – (1:1) complex
$An(OH)_3$	Hydroxide of the actinide (III)
$AnPO_4$	Actinide (III) phosphate
$AnSO_4^+$	Actinide (III) sulfate ion – (1:1) complex
$B_3O_3(OH)_4^-$	Hydroxy polynuclear form of boric acid
$B_4O_7^{2-}$	Tetraborate anion
$B(OH)_x^{3-x}$	Hydroxyborate ions
Ba^{2+}	Barium cation
Br^-	Bromide anion
[C]	Concentration of species C in solution
$[C_0]$	Concentration of a chosen standard state
C	Carbon or concentration
$C_6H_{10}O_5$	Cellulose
CH_4	Methane
$CH_3CO_2^-$	Acetate anion
$(CH_2CO_2)_2C(OH)(CO_2)^{3-}$	Citrate anion
$(CH_2CO_2)_2N(CH_2)_2N(CH_2CO_2)_2^{4-}$	Ethylenediaminetetraacetate (EDTA) anion
$C_2O_4^{2-}$	Oxalate anion
Ca^{2+}	Calcium cation
$CaCl_2$	Calcium chloride
$CaCO_3$	Calcium carbonate
$CaMg(CO_3)_2$	Dolomite, calcium magnesium carbonate

CaO	Calcium oxide
Ca ₄ [Pu(OH) ₈] ⁴⁺	Calcium plutonium (IV) hydroxide cation complex
CaSO ₄	Anhydrite, calcium sulfate
CaSO ₄ ·2H ₂ O	Gypsum, hydrated calcium sulfate
Ca ₄ [Th(OH) ₈] ⁴⁺	Calcium thorium (IV) hydroxide cation complex
CeO ₂	Cerium dioxide
Cl	Chlorine
Cl ⁻	Chloride ion
Cl ₂	Chlorine
Cl ₂ ⁻	Chlorine free radical
Cl ₃ ⁻	Chlorine anion
ClBr ⁻	Chloride bromide radical
ClO ⁻	Hypochlorite anion
ClO ₂ ⁻	Chlorite anion
ClO ₃ ⁻	Chlorate anion
ClO ₄ ⁻	Perchlorate anion
Cm	Curium
Cm(III)	Curium in the +3 oxidation state
Cm(IV)	Curium in the +4 oxidation state
Cm ³⁺	Curium cation – Aqueous form of the curium at the +3 oxidation state
CO ₂	Carbon dioxide
CO ₃ ²⁻	Carbonate anion
Cr	Chromium
Cs	Cesium
Cu	Copper
F ⁻	Fluoride
Fe	Iron
Fe(0)	Zero-valent iron
FeCl ₄ ²⁻	Iron (II) tetrachloride anion
FeCO ₃	Iron (II) carbonate, ferrous carbonate
Fe ₃ O ₄	Magnetite, iron (II,III) oxide
Fe ²⁺	Aqueous form of the iron in the +2 oxidation state, ferrous anion

Fe ³⁺	Aqueous form of the iron in the +3 oxidation state, ferric anion
Fe(II)	Iron in the +2 oxidation state
Fe(III)	Iron in the +3 oxidation state
Fe(OH) ₃	Ferric hydroxide
Fe(OH) ₂ ·(x-2)H ₂ O	Hydrated ferrous hydroxide
FeOOH	Goethite, iron oxide hydroxide
FeS	Iron (II) sulfide
H	Hydrogen
H ⁺	Hydrogen cation
H ₂	Hydrogen
HA	Humic acid
HAal-LBr	Aliphatic humic acid isolated from sediments collected from Lake Bradford, Florida, prepared by Florida State University
HAar-Gor	Aromatic humic acid isolated from groundwaters near Gorleben, Germany, obtained from Professor J.-I. Kim, Institut für Radiochemie, München
HClO ₄	Perchloric acid
hmag.	Hydromagnesite
HPO ₄ ²⁻	Hydrogenphosphate anion
HCO ₃ ⁻	Bicarbonate anion, hydrogen carbonate anion
H ₂ O	Water
H ₂ O ₂	Hydrogen peroxide
HOBr	Hypobromous acid
HOCl	Hypochlorous acid
H ₂ PO ₄ ⁻	Dihydrogen phosphate anion
H ₂ S	Hydrogen sulfide
K	Potassium
K ⁺	Potassium cation
K ₂ MgCa ₂ (SO ₄) ₄ ·2H ₂ O	Polyhalite
KNpO ₂ CO ₃ ·2H ₂ O	Hydrated potassium neptunium (V) carbonate – (1:1:1) complex
K ₃ NpO ₂ (CO ₃) ₂ ·0.5H ₂ O	Hydrated potassium neptunium (V) carbonate – (3:1:2) complex
K ₂ SO ₄	Potassium sulfate
K ₂ U ₂ O ₇	Potassium diuranate

mag.	Magnesite
Mg	Magnesium
Mg ²⁺	Magnesium cation
MgCl ₂	Magnesium chloride
Mg ₃ (OH) ₅ Cl·4H ₂ O	Magnesium chloride hydroxide hydrate
MgCO ₃	Magnesite, magnesium carbonate
Mg ₅ (CO ₃) ₄ (OH) ₂ ·4H ₂ O	Hydromagnesite
Mg ₂ (OH) ₃ Cl·4H ₂ O	Magnesium chloride hydroxide hydrate, magnesium oxychloride
MgO	Periclase, magnesium oxide
Mg(OH) ₂	Brucite, magnesium hydroxide
Mn	Manganese
N ₂	Nitrogen
Na	Sodium
Na ⁺	Sodium cation
Na ₂ SO ₄	Sodium sulfate
Na ₂ S ₂ O ₄	Sodium hydrosulfite
NaAm(CO ₃) ₂	Sodium americium (III) carbonate
NaCl	Halite, sodium chloride
NaNpO ₂ CO ₃ ·3.5H ₂ O	Hydrated sodium neptunium (V) carbonate – (1:1:1) complex
Na ₃ NpO ₂ (CO ₃) ₂	Sodium neptunium (V) carbonate – (3:1:2) complex
NaOH	Sodium hydroxide
NaUO ₂ O(OH) H ₂ O	Clarkeite, sodium uranate
Na ₂ U ₂ O ₇ ·xH ₂ O	Sodium diuranate hydrate
Nd	Neodymium
Nd(III)	Neodymium in the +3 oxidation state
Nd(OH) ₃	Neodymium (III) hydroxide
Ni	Nickel
Ni ²⁺	Nickel (II) cation
Np	Neptunium
Np(IV)	Neptunium in the +4 oxidation state
Np(V)	Neptunium in the +5 oxidation state
Np(VI)	Neptunium in the +6 oxidation state

Np^{4+}	Neptunium cation – Aqueous form of the neptunium at the +4 oxidation state
NpO_2^+ or Np(V)O_2^+	Neptunyl cation – Aqueous form of the neptunium at the +5 oxidation state
NpO_2^{2+} or Np(VI)O_2^{2+}	Neptunyl cation – Aqueous form of the neptunium at the +6 oxidation state
$\text{NpO}_2\text{CO}_3^-$	Neptunium (V) carbonate ion – (1:1) complex
$\text{NpO}_2(\text{CO}_3)_2^{3-}$	Neptunium (V) carbonate ion – (1:2) complex
$\text{NpO}_2(\text{CO}_3)_3^{5-}$	Neptunium (V) carbonate ion – (1:3) complex
NpO_2OH	Neptunium (V) hydroxide
$\text{NpO}_2(\text{OH})_2^-$	Neptunium (V) hydroxide ion – (1:2) complex
NO_3^-	Nitrate anion
N_S	Adsorption site density (sites/nm ²)
O	Oxygen
O_2	Molecular oxygen
OBr^-	Hypobromite anion
OCl^-	Hypochlorite anion
OH^-	Hydroxide anion
$\text{OH}\cdot$	Hydroxyl radical
Pb	Lead
Pb(0)	Zero-valent lead
Pb(II)	Lead in the +2 oxidation state
Pb^{2+}	Lead cation – Aqueous form of the lead at the +2 oxidation state
Pb^{4+}	Lead cation – Aqueous form of the lead at the +4 oxidation state
PbCl_2	Lead (II) chloride
PbCO_3	Lead (II) carbonate
$[\text{Pb}_6\text{O}(\text{OH})_6]^{4+}$	Lead (II) polyoxyhydroxide cation
PbO	Lead (II) oxide
PO_4^{3-}	Phosphate anion
$(\text{PbOH})_2\text{CO}_3$	Lead (II) hydroxide carbonate
PbS	Lead (II) sulfide
PbSO_4	Lead (II) sulfate
Pu	Plutonium

Pu(III)	Plutonium in the +3 oxidation state
Pu(IV)	Plutonium in the +4 oxidation state
Pu(V)	Plutonium in the +5 oxidation state
Pu(VI)	Plutonium in the +6 oxidation state
Pu(VII)	Plutonium in the +7 oxidation state
Pu^{3+}	Plutonium cation – Aqueous form of the plutonium at the +3 oxidation state
Pu^{4+}	Plutonium cation – Aqueous form of the plutonium at the +4 oxidation state
$\text{Pu}(\text{CO}_3)^+$	Plutonium (III) carbonate ion – (1:1) complex
$\text{Pu}(\text{CO}_3)_2^-$	Plutonium (III) carbonate ion – (1:2) complex
$\text{Pu}(\text{CO}_3)_3^{3-}$	Plutonium (III) carbonate ion – (1:3) complex
PuF_2^{2+}	Plutonium (IV) fluoride cation
PuO_2	Plutonium (IV) dioxide
PuO_{2+x}	Oxidized plutonium (IV) dioxide
PuO_2CO_3	Plutonium (VI) carbonate
$\text{PuO}_2\text{CO}_3^-$	Plutonium (V) carbonate ion – (1:1) complex
$\text{PuO}_2(\text{CO}_3)_2^{3-}$	Plutonium (V) carbonate ion – (1:2) complex
$\text{PuO}_2(\text{CO}_3)_2^{2-}$	Plutonium (VI) carbonate ion – (1:2) complex
$\text{PuO}_2(\text{CO}_3)_3^{4-}$	Plutonium (VI) carbonate ion – (1:3) complex
PuO_2F^+	Plutonium (VI) oxofluoride cation
PuO_2^+ or Pu(V)O_2^+	Plutonyl cation – Aqueous form of the plutonium at the +5 oxidation state
PuO_2^{2+} or Pu(VI)O_2^{2+}	Plutonyl cation – Aqueous form of the plutonium at the +6 oxidation state
$\text{PuO}_3 \cdot x\text{H}_2\text{O}$	Plutonium (VI) trioxide-hydrate
PuOH^{3+}	Plutonium (IV) hydroxide cation – (1:1) complex
$\text{Pu}(\text{OH})_2^{2+}$	Plutonium (IV) hydroxide cation – (1:2) complex
$\text{Pu}(\text{OH})_3^+$	Plutonium (IV) hydroxide cation – (1:3) complex
$\text{Pu}(\text{OH})_4$	Plutonium (IV) hydroxide
$[\text{Pu}(\text{H}_2\text{O})_m]^{n+}$	Hydrolysis complex of plutonium
$[\text{Pu}(\text{O})\text{Pu}(\text{O})\text{Pu}(\text{O})\dots]_n$	Plutonium polymer
Ra	Radium
S^{2-}	Sulfide anion

SO_4^{2-}	Sulfate anion
Sr	Strontium
Tc(IV)	Technetium in the +4 oxidation state
Th	Thorium
Th(IV)	Thorium in the +4 oxidation state
Th^{3+}	Thorium cation – Aqueous form of the thorium at the +3 oxidation state
Th^{4+}	Thorium cation – Aqueous form of the thorium at the +4 oxidation state
$\text{Th}(\text{CO}_3)_5^{6-}$	Thorium (IV) pentacarbonyl ion complex
ThO_2	Thorium dioxide
$\text{Th}(\text{OH})_4$	Thorium hydroxide
$\text{Th}(\text{OH})(\text{CO}_3)_4^{5-}$	Thorium (IV) hydroxide carbonate ion – (1:1:4) complex
$\text{Th}(\text{OH})_2(\text{CO}_3)_2^{2-}$	Thorium (IV) hydroxide carbonate ion – (1:2:2) complex
$\text{Th}(\text{OH})_3\text{CO}_3^-$	Thorium (IV) hydroxide carbonate ion – (1:3:1) complex
$\text{Th}(\text{OH})_2\text{SO}_4$	Thorium (IV) hydroxide sulfate ion – (1:2:1) complex
$\text{Th}(\text{SO}_4)_3^{2-}$	Thorium (IV) sulfate ion – (1:3) complex
$\text{Th}(\text{SO}_4)_2$	Thorium (IV) sulfate
U	Uranium
U(III)	Uranium in the +3 oxidation state
U(IV)	Uranium in the +4 oxidation state
U(V)	Uranium in the +5 oxidation state
U(VI)	Uranium in the +6 oxidation state
U^{3+}	Uranium cation – Aqueous form of the uranium at the +3 oxidation state
U^{4+}	Uranium cation – Aqueous form of the uranium at the +4 oxidation state
U_3O_7	Triuranium heptaoxide
U_4O_9	Tetrauranium nonaoxide
UO_2	Uraninite, uranium (IV) dioxide
UO_2^{2+} or $\text{U}(\text{VI})\text{O}_2^{2+}$	Uranyl cation – Aqueous form of the uranium at the +6 oxidation state
UO_2CO_3	Rutherfordine, uranium (VI) carbonate
$\text{UO}_2(\text{CO}_3)_2^{2-}$	Uranium (VI) carbonate ion – (1:2) complex
$\text{UO}_2(\text{CO}_3)_3^{4-}$	Uranium (VI) carbonate ion – (1:3) complex or triscarbonato complex
$(\text{UO}_2)_3(\text{CO}_3)_6^{6-}$	Uranium (VI) carbonate ion – (3:6) complex
$(\text{UO}_2)_2(\text{CO}_3)(\text{OH})_3^-$	Uranium (VI) carbonate hydroxide ion – (2:1:3) complex
$(\text{UO}_2)_{11}(\text{CO}_3)_6(\text{OH})_{12}^{2-}$	Uranium (VI) carbonate hydroxide ion – (11:6:12) complex

UO_2OH^+	Uranium (VI) hydroxide ion – (1:1) complex
$(\text{UO}_2)_3(\text{OH})_5^+$	Uranium (VI) hydroxide ion – (3:5) complex
$\text{UO}_2(\text{OH})_3^-$	Uranium (VI) hydroxide ion – (1:3) complex
$\text{UO}_2(\text{OH})_4^{2-}$	Uranium (VI) hydroxide ion – (1:4) complex
$\text{U}(\text{OH})_3^+$	Uranium (IV) hydroxide ion – (1:3) complex
$\text{U}(\text{OH})_4$	Uranium (IV) hydroxide
$\text{UO}_2 \cdot x\text{H}_2\text{O}$	Hydrous uranium (IV) dioxide
$(\text{UO}_2)(\text{OH})_2 \cdot x\text{H}_2\text{O}$ or $\text{UO}_3 \cdot x\text{H}_2\text{O}$	Schoepite, hydrated uranium trioxide
V	Vanadium
ZrO_2	Zirconium dioxide

1 **SOTERM-1.0 Introduction**

2 Appendix SOTERM-2009 (Actinide Chemistry Source Term) is a summary of the U. S.
3 Department of Energy's (DOE's) understanding of the Waste Isolation Pilot Plant (WIPP)
4 chemical conditions, assumptions, and processes; the underlying actinide chemistry; and the
5 resulting dissolved actinide concentrations that were calculated based on this repository
6 chemistry. This appendix supplements Appendix PA-2009 in the 2009 Compliance
7 Recertification Application (CRA-2009). The calculational results summarized here are based
8 on the 2004 Performance Assessment (PA) Baseline Calculations (PABC) (Leigh et al. 2005),
9 and hence on the various assumptions about chemical conditions in the repository that were
10 included in the formulation of that baseline. WIPP-related geochemical experimental results
11 obtained within and outside of the WIPP project since these calculations were performed are also
12 summarized.

13 Actinide release from the WIPP is a critical performance measure for the WIPP as a transuranic
14 (TRU) repository. There are a number of potential pathways for actinide release considered by
15 the WIPP PA, and these are discussed in detail in Appendix PA-2009. Quantifying the impact of
16 these releases contributes directly to assessing compliance with 40 CFR Part 191 (U.S.
17 Environmental Protection Agency 1993).

18 In the undisturbed scenario for PA, actinide releases up the shafts or laterally through the marker
19 beds are physically insignificant in all realizations and have no impact on compliance (Appendix
20 PA-2009, Section PA-7.2). The self-sealing of the salt and the reducing anoxic environment in
21 the repository provide the primary mechanisms for geologic isolation of the TRU waste in the
22 undisturbed scenario. For the disturbed scenarios, actinide releases can occur primarily as a
23 result of inadvertent human intrusions (i.e., boreholes drilled into or through the repository). For
24 example, direct brine release (DBR) to the accessible environment may occur during a drilling
25 intrusion, or actinides may be transported up a borehole to the Culebra Formation and then move
26 laterally through the Culebra to the land withdrawal boundary (LWB). The potential for human
27 intrusions makes it important to assess the range of possible repository conditions and associated
28 dissolved actinide concentrations associated with the disturbed scenarios.

29 This appendix focuses on the actinide source term used to calculate actinide release from the
30 WIPP for the DBR release and transport through the Salado and Culebra Formations. This
31 actinide source term is the sum of the soluble and colloidal species in brine. Direct release of
32 actinide particulates to the surface resulting from cuttings, cavings, and spillings is not
33 considered part of the actinide source term because these particulate releases do not depend on
34 the mobilized actinide concentrations in brine.

35 The relative importance of radioelements that significantly contribute to the actinide source term,
36 and consequently impact the long-term performance of the WIPP, as established in the 2004
37 Compliance Recertification Application (CRA-2004) (U.S. Department of Energy 2004),
38 Appendix SOTERM, and the CRA-2004 PABC is:

39
$$\text{Pu} \approx \text{Am} \gg \text{U} > \text{Th} \gg \text{Np, Cm, and fission products.} \quad (\text{SOTERM.1})$$

1 The TRU components for this list of radionuclides are the α -emitting isotopes of plutonium (Pu),
2 americium (Am), neptunium (Np), and curium (Cm) with half-lives greater than 20 years. These
3 TRU actinides make up the waste unit factor used to calculate the normalized release from the
4 WIPP in U.S. Environmental Protection Agency (EPA) units, as required by Part 191. In
5 SOTERM, the chemistry of thorium (Th) and uranium (U) is also discussed, since these actinides
6 are present in the WIPP waste and their chemistry is analogous to the TRU components.

7 This appendix has the following overall organization:

- 8 • An overview of key near-field conditions and biogeochemical processes is presented in
9 Section SOTERM-2.0.
- 10 • An updated literature review and summary of WIPP-relevant results for the key actinides
11 is given in Section SOTERM-3.0.
- 12 • A summary of the WIPP actinide PA approach and assumptions, along with the
13 calculated actinide solution concentrations, are provided in Section SOTERM-4.0.
- 14 • The PA implementation of the dissolved and colloidal components of the source term is
15 described in Section SOTERM-5.0.

16 Each of these sections identifies important changes and/or new information since the CRA-2004
17 and the CRA-2004 PABC (Leigh et al. 2005).

1 **SOTERM-2.0 Expected WIPP Repository Conditions, Chemistry,** 2 **and Processes**

3 The preemplacement and postemplacement near-field processes and conditions that could affect
4 actinide concentrations in the WIPP are discussed in this section. An up-front summary of the
5 current WIPP chemistry model assumptions is given in Table SOTERM-1, with a more detailed
6 discussion of each assumption presented in the following sections. Emphasis is placed on how
7 these processes and conditions in the repository could affect the concentrations of dissolved and
8 colloidal actinide species in brine.

9 **SOTERM-2.1 Ambient Geochemical Conditions**

10 The ambient geochemical conditions are discussed in detail in the CRA-2004, Chapter 6.0. The
11 Salado, which is the repository horizon, is predominantly pure halite (NaCl), with interbeds
12 (marker beds) consisting mainly of anhydrite (CaSO₄). The nearly pure halite contains accessory
13 evaporite minerals such as anhydrite (CaSO₄), gypsum (CaSO₄·2H₂O), polyhalite
14 (K₂MgCa₂(SO₄)₄·2H₂O), magnesite (MgCO₃), and clays. Small quantities of intergranular
15 (grain-boundary) brines and intragranular brines (fluid inclusions) are associated with the salt at
16 the repository horizon. These brines are highly concentrated solutions (ionic strength up to 8
17 moles per liter [M]) of predominantly sodium (Na⁺), magnesium (Mg²⁺), potassium (K⁺),
18 chloride (Cl⁻), and sulfate (SO₄²⁻), with smaller amounts of calcium (Ca²⁺), carbonate (CO₃²⁻),
19 and borate (B(OH)₄⁻ and/or B₄O₇²⁻). These brines have been in contact with the Salado evaporite
20 minerals since their deposition (estimated to be 250 million years) and are saturated with respect
21 to these minerals.

22 Underlying the Salado Formation is the Castile, composed of alternating units of interlaminated
23 carbonate, anhydrite, and nearly pure halite. The Castile in the vicinity of the WIPP site is
24 known to contain localized brine reservoirs with sufficient pressure to force brine to the surface
25 if penetrated by a borehole. Castile brines are predominantly saturated NaCl solutions
26 containing Ca²⁺ and SO₄²⁻, as well as small concentrations of other elements, and are about eight
27 times more concentrated than seawater. Overlying the Salado in the vicinity of the WIPP site is
28 the Culebra of the Rustler Formation, a fractured dolomite (CaMg(CO₃)₂) layer. It is significant
29 because it is expected to be the most transmissive geologic pathway to the accessible
30 environment. Culebra brines are generally more dilute than the Salado and Castile brines, and
31 are predominantly NaCl with K⁺, Mg²⁺, Ca²⁺, SO₄²⁻, and CO₃²⁻. More detailed information on
32 the distribution of Culebra brine salinity in the WIPP site and vicinity can be found in Appendix
33 HYDRO-2009.

34 **SOTERM-2.2 Repository Conditions**

35 Repository conditions that could potentially affect actinide solubility are briefly summarized in
36 this section. These include: repository pressure, repository temperature, water content and
37 relative humidity, the minimum free volume for actinide release (effective porosity), and the
38 extent of the disturbed rock zone (DRZ).

1 **Table SOTERM-1. Summary of Current WIPP Chemistry Model Assumptions**
 2 **(Leigh et al. 2005)**

Repository Condition or Parameter	CRA-2004/CRA-2004 PABC Assumptions	SOTERM-2009 Section Containing References
Ambient Geochemistry	Predominantly halite of the Salado Formation, with anhydrite interbeds and inclusions.	SOTERM-2.1
Temperature	Ambient temperature is 28 °C (82 °F). An increase of up to 3 °C (5.4 °F) is possible as a result of the emplacement of TRU waste.	SOTERM-2.2.2
Humidity	~70 percent (%) relative humidity (RH) at the repository temperature.	SOTERM-2.2.3
Water Content	Host rock is groundwater-saturated with inclusions in the salt that range from 0.057% to 3% by mass. Repository is unsaturated for up to 1000 years (yr) depending on pressure and intrusion scenarios.	SOTERM-2.2.3
Pressure	A lithostatic pressure of about 15 megapascals (MPa) (148 atmospheres [atm]) at repository depth; a hydrostatic pressure of about 8 MPa (79.0 atm) at the bottom of an intrusion borehole at repository depth.	SOTERM-2.2.1
Gas Phase	Initially air/oxic at repository closure, but rapidly transitions to an anoxic atmosphere dominated by hydrogen with smaller amounts of methane and nitrogen. Trace amounts of carbon dioxide, hydrogen sulfide, and other microbially produced gases may be present.	SOTERM-2.2.3 SOTERM-2.4.1
DRZ	Upper bound of 12 meter (m) above the repository and 2 m below the repository horizon.	SOTERM-2.2.5
Minimum Brine Volume for DBR	The calculated minimum volume of brine from any source needed for DBR release is 10011 cubic meters (m ³).	SOTERM-2.2.4
WIPP Brine	High-ionic-strength brine bracketed by Generic Weep Brine (GWB) and ERDA-6 brine formulations	SOTERM-2.3.1
pH	pH of about 9 and controlled by MgO, borate, and carbonate.	SOTERM-2.3.2
MgO	Engineered barrier for the WIPP that will sequester carbon dioxide (CO ₂) and control increases and decreases in pH by the precipitation of brucite, hydromagnesite, and magnesite.	SOTERM-2.3.3
Microbial Effects	Gas generation, primarily carbon dioxide and hydrogen sulfide, resulting from the biodegradation of cellulosic, plastic, and rubber (CPR) materials and creation of reducing conditions, including bioreduction of actinide elements from higher oxidation states.	SOTERM-2.4.1
Corrosion	Container steel and metals in WIPP waste will react to remove oxygen and produce hydrogen.	SOTERM-2.3.4
Radiolysis	Localized oxidizing effects possible near high-activity actinides, but overall radiolytic processes are overwhelmed by the in-room chemistry.	SOTERM-2.4.2

3

1 **SOTERM-2.2.1 Repository Pressure**

2 The preexcavation lithostatic pressure (Stein 2005, CRA-2004 PABC, Section 4.1.1) in the
3 WIPP at repository depth is about 15 MPa (148 atm). This pressure can be reestablished after
4 repository closure due to salt creep and gas generation, but there are a number of PA vectors that
5 predict pressure may not be fully restored even by the end of the 10,000-yr period of WIPP
6 performance, and final pressures may range from 6 to 15 MPa (in the undisturbed scenario) and
7 from 0.1 to 15 MPa (in the disturbed scenarios) considered in the CRA-2004 PABC. In this
8 context, the pressure in the repository after closure cannot significantly exceed the far-field
9 confining stress of about 15 MPa.

10 DBR can occur when the pressure in the repository at the time of a drilling intrusion exceeds 8
11 MPa and a sufficient amount of brine has already flowed into the repository (see related
12 discussions in Section SOTERM-2.2.4 and Stein 2005). Eight MPa is the pressure exerted by a
13 column of brine-saturated drilling fluid at the depth of the repository (Stoelzel and OBrien 1996).
14 For repository pressures less than 8 MPa, no DBRs are assumed to occur because the fluid
15 pressure in the repository cannot eject the drilling fluid from the borehole. There is also no DBR
16 release until the brine volume exceeds the minimum brine volume (see Section SOTERM-2.2.4)
17 needed to fill the effective porosity present in the compacted TRU waste.

18 When discussing the possible range of brine pressure to the source term, it is important to assess
19 the possibility that the pressures experienced in the WIPP could impact actinide solubilities. In
20 this context, the maximum pressure possible (~15 MPa) is well below pressures needed to affect
21 the solution chemistry, and is not expected to have a significant effect on actinide solubilities or
22 processes that lead to the association of actinides with colloidal particles. For these reasons, the
23 effect of pressure on actinide solubility is not considered in the WIPP PA.

24 **SOTERM-2.2.2 Repository Temperature**

25 The ambient preemplacement temperature at the WIPP repository horizon was established to be
26 28 °C (82 °F) (Munson et al., 1987). The emplacement of TRU waste in the WIPP is expected to
27 increase the ambient temperature by only a few degrees Celsius at most (Sanchez and Trelue
28 1996, Wang and Brush 1996a). For the purposes of PA, the temperature of the WIPP
29 underground repository is assumed to be constant with time at 300 Kelvin (K) (27 °C [80 °F])
30 (Appendix PA-2009).

31 Actinide solubilities were calculated in WIPP PA using thermodynamic and laboratory data
32 measured at 25 °C [77 °F]. The expected effect of the slightly elevated temperature in the WIPP
33 on actinide concentrations is relatively small, especially when compared to other uncertainties
34 inherent in the measurement and calculation of the actinide solubilities and colloidal
35 concentrations. For this reason, the very small effect of temperature on actinide solubility was
36 not considered in WIPP PA calculations.

37 **SOTERM-2.2.3 Water Content and Relative Humidity**

38 A key argument for the WIPP as a TRU waste repository is that the self-sealing of the salt will
39 limit the availability and transport of water into and through the repository, and correspondingly

1 minimize the potential release of TRU from the repository. In all the undisturbed repository
2 scenarios considered by PA, no actinide release from the WIPP is predicted (Leigh et al. 2005).
3 There is, however, groundwater in the WIPP, even in undisturbed scenarios, that is potentially
4 available to interact with the TRU waste. The salt surrounding waste is groundwater-saturated
5 with both intergranular and intragranular water. The amount of water present as inclusions in the
6 salt was used as a random variable in PA calculations (Leigh et al. 2005) with a range of 0.057 to
7 3 mass % based on what was measured in preexcavation salt (Skokan et al. 1987 and Powers et
8 al. 1978). This brine can seep into the repository horizon and fill the excavated areas (TRU
9 waste). Brine saturation of the repository is estimated to occur in less than 1000 years after
10 repository closure.

11 The presence of some brine in the WIPP prior to brine saturation leads to an environment that
12 will contain an atmosphere of up to about 70% RH, defined by the vapor pressure of saturated
13 brine at the repository temperature. This water vapor pressure will be present, at least in part,
14 until brine saturation occurs as a result of some human intrusions or brine seepage into the
15 excavated area.

16 The presence of a humid environment in the WIPP prior to brine saturation may have a transitory
17 effect on actinide solubilities. These transitory/temporary phases are not considered in WIPP PA
18 because they will be rapidly overwhelmed by the in-room chemistry and higher reactivity of the
19 waste components should brine inundation or saturation occur.

20 **SOTERM-2.2.4 Minimum Repository Brine Volume**

21 The minimum brine volume is the volume of brine needed for a DBR to occur during an
22 intrusion scenario. There have been two calculational efforts to estimate this volume in the
23 compacted TRU waste for the WIPP. Prior to the 1996 Compliance Certification Application
24 (CCA) (U.S. Department of Energy 1996), Larson (1996) estimated this volume, calculated at
25 2000 years after repository closure with an assumption of no gas generation, to be 343 m³ per
26 room and a minimum brine saturation of 0.75 for 116 equivalent rooms. This led to a repository-
27 scale volume of 29,841 m³. Under these assumptions, this was the minimum brine volume
28 needed for DBR.

29 Since this initial calculation, new information has led to a reassessment of this minimum volume
30 (Stein 2005). The most important changes in this new calculation were: (1) it was based on the
31 structural results used in the most current PA, (2) the time of the calculation was extended from
32 2000 to 10,000 years after repository closure, (3) a corrected waste-filled repository volume was
33 used, and (4) the calculation was made to be more in line with the DBR conceptual model that
34 requires a hydrostatic pressure of about 8 MPa. These changes led to a calculated per-room
35 volume of 301.5 m³, a reduction in the minimum brine saturation value to 0.276, and 120.3
36 equivalent rooms. This led to an overall repository-scale volume of 10,011 m³.

37 The minimum repository brine volume has two important potential impacts on calculating
38 actinide concentrations in the WIPP. The first is that the predicted inventory of some actinides,
39 when fully dissolved in this brine volume, lead to concentrations that are below their predicted
40 solubility, most importantly Np and Cm. In this context, they are assumed to be fully dissolved
41 in the brine and may have an insignificant impact on the calculated actinide release in WIPP PA

1 based on inventory arguments alone. The second impact is on the predicted concentration of key
2 organic and inorganic complexants that coexist with the TRU species in WIPP waste. The
3 maximum concentrations of acetate, citrate, and ethylenediaminetetraacetic acid (EDTA) (see
4 Section SOTERM-2.3.6) are defined by their fully dissolved concentration in the minimum brine
5 volume.

6 **SOTERM-2.2.5 DRZ**

7 More detailed discussions of the DRZ can be found in Appendix PA-2009. The DRZ is a zone
8 immediately surrounding the excavated repository that has been altered by the construction of
9 the repository. In the Brine and Gas Flow (BRAGFLO) code, the Upper DRZ has a height of
10 about 12 m (39 feet [ft]) and the Lower DRZ has a depth of about 2.2 m (7.2 ft) (Leigh et al.
11 2005, Figure 4-1). The creation of this DRZ disturbs the anhydrite layers and marker beds and
12 alters the permeability and effective porosity of the rock around the excavated areas, providing
13 enhanced pathways for the flow of gas and brine between the waste-filled rooms and the nearby
14 interbeds.

15 The DRZ is important to the calculation of dissolved actinide concentrations because it
16 potentially makes the minerals in the interbeds “available” for reaction with the TRU and
17 emplaced waste components. The most important of these minerals is the calcium sulfate
18 (anhydrite) that could function as a source of sulfate for processes in the repository subsequent to
19 brine inundation. Currently, sulfate is assumed to be available from the DRZ into the waste area,
20 which prolongs microbial sulfate reduction processes in the WIPP.

21 **SOTERM-2.3 Repository Chemistry**

22 Brine present in the WIPP will react with emplaced TRU waste, waste components, and
23 engineered barrier materials to establish the brine chemistry that will define actinide solubilities
24 and colloid formation. In this context, the composition of the brine in the repository horizon will
25 be defined by a combination of factors, including the initial composition of the in-flow brine;
26 reactions that control pH; and the extent to which this brine is altered by equilibration with the
27 waste components, emplaced container materials, and the waste-derived organic chelating agents
28 that can dissolve in the brine. An overview of this repository chemistry is given in this section.

29 **SOTERM-2.3.1 WIPP Brine**

30 The composition of brine in and around the WIPP site prior to waste emplacement was
31 established by sampling the groundwater and intergranular inclusions in the Salado and Castile
32 (Popielak et al. 1983, Snider 2003a). Synthetic brines that simulate these compositions were
33 developed and have been used for WIPP laboratory studies. The two simulated brines that best
34 represent these repository-relevant, end-member brines are: (1) GWB, which simulates
35 intergranular (grain-boundary) brines from the Salado at or near the stratigraphic horizon of the
36 repository (Snider 2003a); and (2) ERDA-6, which simulates brine from the ERDA-6 well,
37 typical of fluids in Castile brine reservoirs (Popielak et al. 1983). The concentrations of key
38 inorganic species in these two brines, along with some brine properties, are listed in Table
39 SOTERM-2.

1 **Table SOTERM-2. Compositions of GWB and ERDA-6 Prior To and After Equilibration**
 2 **with MgO (Brush et al. 2006)**

Ion or Property ^a	GWB ^b Before Reaction with MgO, Halite, and Anhydrite	GWB After Reaction with MgO, Halite, and Anhydrite ^c	ERDA-6 ^d Before Reaction with MgO, Halite, and Anhydrite	ERDA-6 After Reaction with MgO, Halite, and Anhydrite ^c
B(OH) _x ^{3-x} (see Footnote e)	158 mM	166 mM	63 mM	62.4 mM
Na ⁺	3.53 M	4.35 M	4.87 M	5.24 M
Mg ²⁺	1.02 M	0.578 M	19 mM	157 mM
K ⁺	0.467 M	0.490 M	97 mM	96.1 mM
Ca ²⁺	14 mM	8.95 mM	12 mM	10.7 mM
SO ₄ ²⁻	177 mM	228 mM	170 mM	179 mM
Cl ⁻	5.86 M	5.38 M	4.8 M	5.24 M
Br ⁻	26.6 mM	27.8 mM	11 mM	10.9 mM
Total Inorganic C (as HCO ₃ ⁻)	Not reported	0.35 mM	16 mM	0.428 mM
pH	Not reported	8.69	6.17	8.94
Relative Density	1.2	1.23	1.22	1.22
Ionic Strength (m)	7.56	7.66	6.05	6.80

^a Ions listed represent the total of all species with this ion.

^b From Snider (2003a)

^c From Brush et al. (2006)

^d From Popielak et al. (1983)

^e Boron species will be present in brine as boric acid, hydroxy polynuclear forms (B₃O₃(OH)₄⁻, and/or borate forms (e.g., B₄O₇²⁻)

3
 4 At the time of the CCA, Brine A (Molecke 1983) and Salado Primary Constituents (SPC) Brine,
 5 a version of Brine A from which trace elements had been removed, were used to simulate Salado
 6 brines for laboratory and modeling studies. Since the CCA, however, GWB has been shown to
 7 be more representative of intergranular Salado brines than either Brine A or SPC Brine (Brush
 8 and Xiong 2003a, Snider 2003a). This brine formulation is currently used to represent Salado
 9 brines in PA. In particular, the magnesium concentration of GWB (1.0 M) simulates the average
 10 concentration of this element in Salado brines more closely than Brine A (1.44 M).

11 The reaction with MgO, based on the modeling calculations performed, leads to some potentially
 12 significant changes in the composition of the brine (see Table SOTERM-2). The most important
 13 of these changes for GWB brine is the lowering of the magnesium concentration from 1.02 to
 14 0.578 M, a decrease in calcium concentration from 14 to 8.95 mM, and a pH of 8.69. For
 15 ERDA-6, there is a significant increase in the magnesium concentration from 19 to 157 mM, a
 16 decrease in total inorganic carbon from 16 to 0.428 mM, and an increase of the pH to 8.94 from
 17 6.17. The pH associated with these MgO-reacted brines established the range of expected pH
 18 values in the WIPP for the calculation of actinide solubilities, and the composition of these
 19 reacted brines were used in PA to calculate actinide solubility in brine (Brush 2005).

1 Salado brine will enter the repository after closure, and can be supplemented by Castile brine in
2 some human intrusion scenarios. It is also possible that groundwater from the Rustler and
3 Dewey Lake Formation could flow down the borehole into the repository, mix with the waste,
4 and then be forced back up a borehole. The majority of WIPP-specific solubility studies since
5 the CRA-2004 were performed using GWB or ERDA-6 brines, since these brines bracket the
6 expected range in brine composition. Including brine mixing in PA has been considered and
7 rejected because using the end member brines (i.e., GWB or ERDA-6 brines) brackets the
8 median values and uncertainties for the solubility calculations.

9 In addition to using these end-member brines in PA, other simplifying assumptions were also
10 made:

- 11 1. Any brine present in the repository is well mixed with waste.
- 12 2. Equilibria with halite and anhydrite, the most abundant Salado minerals at or near the
13 stratigraphic horizon of the repository, are rapidly established.
- 14 3. Oxidation-reduction (redox) equilibria with waste materials were not assumed.
- 15 4. Brine compositions attained after equilibration of GWB or ERDA-6 with the MgO
16 engineered barrier exist for the entire 10,000-year regulatory period.

17 Brine composition is important to the calculation of actinide concentrations. The inorganic
18 complexants, ionic strength, and pH are direct inputs needed to calculate actinide solubilities for
19 a given brine composition. These species and properties are also important in defining the
20 potential for colloid formation in the WIPP.

21 **SOTERM-2.3.2 Brine pH and pH Buffering**

22 The brine pH is a very critical parameter in defining the solubility of actinides under conditions
23 where brine-mediated releases (DBR and transport through the Culebra) would be important in
24 the WIPP. The brine pH is established by a number of highly coupled processes that will occur
25 when the emplaced WIPP waste is inundated with brine. The most important of these are the
26 potential buffering capacity of the brine coming into the WIPP, the reactions of this brine with
27 emplaced waste components (most notably reduced metals and MgO), and microbial processes.
28 The reactions of the emplaced MgO barrier material are expected to sufficiently control and
29 define the pH when the repository is saturated with brine.

30 The range of brine composition that is likely to be present in the WIPP repository was discussed
31 in Section SOTERM-2.3.1 (see also Table SOTERM-2). These brines have an intrinsic
32 buffering capacity that is highest at pH 8.5-9. ERDA-6 brine, although it has an ambient pH of
33 6.2, contains a number of constituents that, in the pH range of 8-10, add buffer capacity to the
34 reacted brine: Carbonate/bicarbonate (16 mM), borate (63 mM), and divalent cations that tend to
35 react with hydroxide or carbonate to influence pH (Ca^{2+} at 12 mM, and Mg^{2+} at 19 mM). The
36 pK_a for boric acid and dissolved carbonate/bicarbonate species are 9.0 and 9.67, respectively,
37 which explains the tendency of this brine to maintain the pH in the range of 8-10. Operationally,
38 the simulated ERDA-6 brines prepared in the laboratory have relatively high buffering capacity,

1 and significant changes in brine concentrations and pH are not routinely observed once the pH is
 2 experimentally defined (Borkowski et al. 2008, Lucchini et al. 2009). An operational pH range
 3 for ERDA-6 has been defined as having an upper limit of pH ~10, which is the pH at which a
 4 cloud point (indicating Mg precipitation) is observed. The preexcavation ambient ERDA-6-like
 5 brine will naturally add to the buffering capacity of WIPP brine due to its acid-base components
 6 and will establish a relatively high buffer capacity at the mildly alkaline conditions expected in
 7 the WIPP.

8 The expected pH in the WIPP in the event of brine saturation, however, will be defined by the
 9 reaction of the Castile ERDA-6-like brine with the waste components and barrier material. This
 10 was evaluated as part of the documentation for the CRA-2004 PABC (Leigh et al. 2005, Brush et
 11 al. 2006, and Table SOTERM-2).

12 Under these repository-relevant conditions, the expected pH, when little or no carbonate is
 13 present, is 8.69 in GWB brine and 8.94 for ERDA-6 brine. In both cases, this pH is
 14 established/buffered by the brucite dissolution reaction. The presence of microbial activity will
 15 potentially contribute significant amounts of carbon dioxide and leads to a model-predicted pH
 16 of 8.69 and 9.02 for GWB and ERDA-6 brine, respectively.

17 The key role MgO has in the buffering of pH at 8 to 9 under WIPP-relevant conditions is the
 18 basis of current WIPP actinide solubility calculations. In the absence of significant amounts of
 19 CO₂, the following carbonation reaction will buffer the fugacity of carbon dioxide (f_{CO₂}) at a
 20 value of 10^{-5.48} atm in GWB and 10^{-6.15} atm in ERDA-6:

22 Under these conditions, the following brucite dissolution/precipitation reaction will buffer pH in
 23 the WIPP at a value of 8.69 in GWB and 8.94 in ERDA-6 (Brush et al. 2006).

25 The potential for significant CO₂ formation as the result of microbial activity changes the
 26 mechanism by which pH is buffered, but causes a relatively small change in the calculated pH
 27 for ERDA-6-like brines. Microbial consumption of CPR materials could produce significant
 28 quantities of CO₂, which could in turn acidify any brine present in the repository and increase the
 29 solubility of the actinides relative to that predicted for near-neutral and mildly basic conditions.
 30 Under these conditions, both laboratory and modeling studies predict that the following
 31 carbonation reaction:

33 will buffer f_{CO₂} at a value of 10^{-5.50} atm in both GWB and ERDA-6. In this reaction, Mg(OH)₂ is
 34 the brucite, which is the main hydration product of the periclase (MgO) expected in the WIPP;
 35 Mg₅(CO₃)₄(OH)₂·4H₂O is the form of the hydromagnesite expected in the repository.
 36 Consideration of the possibility of high CO₂ levels leads to a calculated pH of 8.69 and 9.02 for
 37 GWB and ERDA-6 brine, respectively. This is a relatively small change in the predicted pH
 38 with no change predicted in GWB brine and only a 0.08 pH shift in ERDA-6 brine. These values

1 of f_{CO_2} and pH were used in the actinide speciation and solubility calculations for all CRA-2004
2 PABC vectors (Brush 2005).

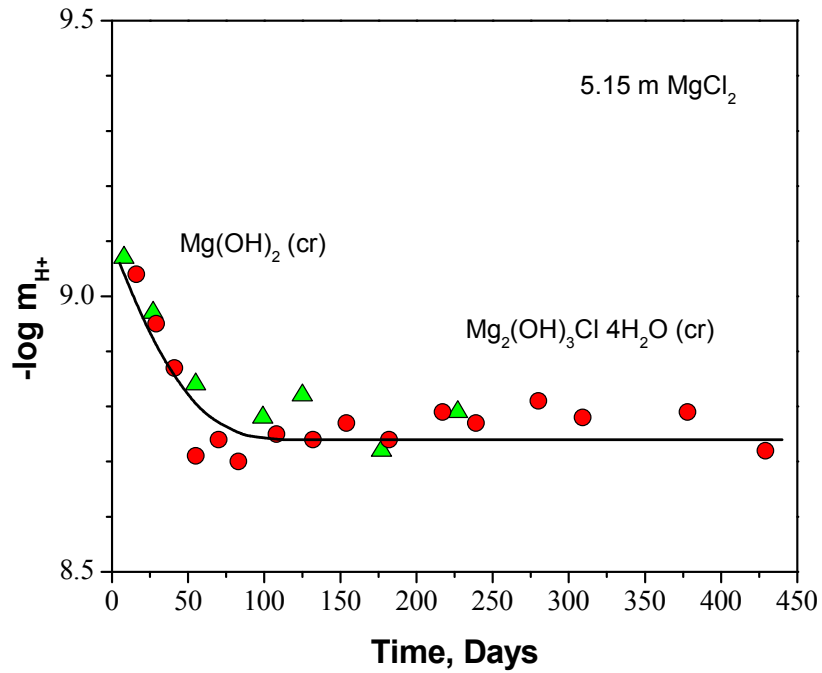

3 Experiments that are relevant to the chemistry and pH buffering capacity of MgO, but not
4 reflected in the CRA-2004 PABC, were performed by investigators at Karlsruhe (Schuessler et
5 al. 2001 and Altmaier et al. 2003). This research was done to support the development of the
6 German salt-based repository where MgO, calcium oxide (CaO), and clays are being evaluated
7 as potential backfill material. Equilibration experiments with 2.67 and 5.15 molal magnesium
8 chloride with excess magnesium hydroxide present were conducted for durations of over 400
9 days and show the establishment of a stable magnesium solution concentration with a pH of 8.7
10 to 8.8, which is in excellent agreement with current WIPP model predictions (see Figure
11 SOTERM-1). This equilibration was also modeled using the Pitzer formulation in the software
12 package for geochemical modeling of aqueous systems (EQ3/6), and excellent agreement was
13 obtained. In this study, a change in magnesium (Mg) concentration was not noted during the
14 equilibration with MgO, even though cement was dissolved in brine.

15 Based on Figure SOTERM-1, the dissolution of MgO in brine, when high chloride
16 concentrations are present (> 2 m), demonstrates the self-buffering property of the brine-MgO
17 system. The pH does not increase when MgO is dissolved. Moreover, with time, the system
18 counteracts the potential decrease in pH that could result from solid phase transformations. To
19 illustrate this better, the dissolution of 1 mole of MgO introduces 1 mol of Mg^{2+} and 2 moles of
20 OH^- to the brine, which should increase the pH. To counter this and maintain pH, the
21 magnesium chloride hydroxide hydrate ($\text{Mg}_2(\text{OH})_3\text{Cl}\cdot 4\text{H}_2\text{O}$) phase precipitates to reduce the pH.
22 For the data shown in Figure SOTERM-1, the pH is reduced slowly as a consequence of
23 equilibration with MgO. In this context, more hydroxide ions are precipitated than are
24 introduced to the brine during the MgO dissolution step. There will also be more magnesium
25 precipitated from the brine, resulting in a lower magnesium concentration in the brine.

26 There are no new WIPP-specific results to report that explicitly address the MgO buffering of
27 WIPP brine since the CRA-2004. Some WIPP-specific experiments using simulated GWB and
28 ERDA-6 brine, however, indirectly provide some information on this subject (Xiong and Lord
29 2008, Lucchini et al. 2009, Borkowski et al. 2008, Reed et al. 2009). A considerable number of
30 the solubility experiments were performed in the pH range of 8-10 (below the cloud point of
31 either ERDA-6 or GWB brine) and reflect strong buffering with no pH drift over the greater
32 than 2-year duration of the experiments. Additionally, no significant Mg precipitation was noted
33 in this pH range. The brines in these solubility studies were not equilibrated with MgO, but in
34 some cases had excess iron in the system. Several experiments were performed outside of this
35 pH range; in the presence of high carbonate (10 mM), a slow, downward pH drift was observed
36 that was as much as 2 pH units over the duration of the experiments, even through
37 preequilibration at the desired higher experimental pH was initially performed. In Xiong and
38 Lord (2008), where the MgO and brucite reaction paths in GWB, ERDA-6 brine, and simplified
39 brines were investigated, the equilibrium pH values measured were pH about 9 and were
40 established by the reaction/dissolution of the MgO or $\text{Mg}(\text{OH})_2$. Slightly higher pH was noted
41 (up to pH 9.7) in some simplified brines when no carbonate or other brine components were
42

1 present. All of these data, although indirect, suggest that the MgO controls the pH to a $\text{pH} = 9 \pm$
2 1. In this context, it is predicted that brine pH will remain in the range of 8-10 under a wide
3 range of expected conditions. These experimental observations are also consistent with the
4 experimental results and model predictions reported by Altmaier et al. (2003).

5 **SOTERM-2.3.3 Selected MgO Chemistry and Reactions**

6 MgO is the bulk, granular material emplaced in the WIPP as an engineered barrier. The MgO
7 currently being placed in the WIPP contains 96 ± 2 mol % reactive constituents (i.e., periclase
8 and lime) (Deng et al. 2006). The amount of MgO emplaced in the WIPP is currently calculated
9 based on the estimated CPR content with an excess factor of 1.2, and it is estimated that in
10 excess of 75,000 metric tons will be emplaced in the WIPP by the time of repository closure.

11 The chemistry of MgO is critical to the overall performance of the WIPP and is discussed in
12 detail in Appendix MgO-2009 and in Xiong and Lord (2008). The MgO, as an engineered
13 barrier in the WIPP repository design, has two important functions that directly support the PA
14 calculation of actinide concentrations in brine. These are:

- 15 1. Sequester the excess CO_2 produced by the microbial consumption of CPR material and
16 establish/maintain a low f_{CO_2} in the repository. This is currently estimated to be $10^{-5.5}$ atm for
17 GWB and ERDA-6 brine.
- 18 2. Establish and buffer the brine pH by maintaining a magnesium solution concentration that
19 reacts with CO_2 and hydroxide (see reaction SOTERM.2 and SOTERM.3) to buffer the pH at
20 about 9. This was part of the pH discussion in Section SOTERM-2.3.2. This buffering
21 removes uncertainty from the actinide concentration calculations.

22 Initially, MgO will undergo hydration to generate brucite ($\text{Mg}(\text{OH})_2$). In time, brucite will react
23 further to form magnesium chloride hydroxide hydrate ($\text{Mg}_3(\text{OH})_5\text{Cl}\cdot 4\text{H}_2\text{O}$) in Salado brine
24 (Appendix MgO-2009, Section MgO-4.1). These phases combine to control the concentration of
25 magnesium in high-magnesium brine (for example, GWB). The existence of magnesium as an
26 aqueous cation in equilibrium with excess magnesium minerals helps to establish the solution pH.

27 For the reaction of MgO with GWB brine, PA uses a magnesium concentration of ~ 0.6 M (see
28 Table SOTERM-2), which is supported by experimental results showing a magnesium
29 concentration ~ 0.7 M (Snider 2003b). This reaction was also investigated by Altmaier et al.
30 (2003) and Harvie, Møller, Weare (1984). Snider noted that the rate of MgO hydration is most
31 likely linked to mineral phase changes between hydrated magnesium oxychloride and brucite.
32 The existence of the hydrated magnesium oxychloride phase was inferred from scanning electron
33 microscope (SEM) images, coupled with an energy dispersive x-ray spectroscopy system (EDS),
34 to identify Mg-Cl phases. The Altmaier and Harvie studies showed that the hydration reaction
35 was a solid-phase transformation between brucite and hydrated magnesium oxychloride that
36 depends not on magnesium concentration, but on chloride concentration, with an invariant point
37 predicted at 1.8 m MgCl concentration and a $-\log m_{\text{H}^+} = 8.95$.

38 The most important role of the MgO engineered barrier is to sequester carbon dioxide to
39 maintain a low f_{CO_2} in the repository. Microbial consumption of CPR materials could produce

1 significant quantities of CO₂. Under these conditions, brucite and magnesium chloride hydroxide
2 hydrate will react with the CO₂ generated. Both laboratory and modeling studies predict that the
3 following carbonation reaction will buffer f_{CO₂} at a value of 10^{-5.50} atm in both GWB and
4 ERDA-6:

6 This reaction effectively removes excess CO₂ from the repository and bicarbonate/carbonate
7 from the brine. The initial product of MgO carbonation reaction is Mg₅(CO₃)₄(OH)₂·4H₂O. This
8 is converted into MgCO₃, which is the expected stable mineral form of magnesium carbonate in
9 the WIPP, according to Reaction (SOTERM.6).

11 Reaction (SOTERM.6) is slow and it is estimated that hundreds to thousands of years (Appendix
12 MgO-2009) are needed for the conversion of hydromagnesite to magnesite. Consumption of CO₂
13 will prevent the brine acidification, and magnesium carbonate precipitation will maintain low
14 carbonate concentration in the WIPP brine to avoid the formation of highly soluble actinide
15 species with carbonate complexes. Although MgO will consume essentially all CO₂, residual
16 quantities in equilibrium with magnesite under the WIPP conditions will persist in the aqueous and
17 gaseous phases.

18 The importance of magnesium chemistry, and correspondingly the chemistry associated with the
19 emplaced MgO on the calculation of actinide concentrations in brine is clear. MgO sequesters
20 CO₂ and minimizes the buildup of carbonate in brine. At the expected pH, carbonate forms
21 strong complexes with the An(III), An(IV), and An(VI) oxidation states. An increased carbonate
22 concentration in brine would significantly increase actinide solubilities. Additionally, MgO
23 helps establish the pH in brine. The removal of CO₂ prevents a decrease in the pH that could
24 also significantly increase actinide solubility. An additional beneficial effect of MgO is to
25 maintain a solution concentration of Mg²⁺ that will precipitate as brucite to keep the pH in the 8-
26 10 range. The presence of MgO leads to a more predictable chemistry that lowers the
27 uncertainty when calculating actinide concentrations in WIPP brine (see Borkowski et al. 2008
28 for data on An(III) and Altmaier et al. 2005 for data on An(IV)).

29 **SOTERM-2.3.4 Iron Chemistry and Corrosion**

30 The WIPP repository will contain a large quantity of reduced iron due to the use of iron-based
31 containers for much of the emplaced TRU waste. Currently, it is estimated that the WIPP will
32 contain upwards of 51,000 metric tons of iron (U.S. Department of Energy 2006) when all the
33 waste is emplaced. The presence of this reduced metal will have an important role in the
34 establishment of reducing conditions in the WIPP by removing oxygen. Reduced iron species
35 (aqueous Fe(II) and Fe(0, II)-valent minerals) are important because they will reduce higher-valent
36 actinides in the WIPP, leading to lower actinide solubilities (Reed et al. 2009, Reed et al. 2006).

37 It is expected that oxic corrosion of steels and aerobic microbial consumption of CPR materials
38 will quickly consume the limited amount of oxygen (O₂) trapped within the repository at the time
39 of closure. After O₂ is consumed, anoxic corrosion of metals will occur (Brush 1990, Brush

1 1995, Wang and Brush 1996a). In all of the vectors for the 2004 PA, the EPA's CCA 1997
 2 Performance Assessment Verification Test (PAVT), the CCA PA, and the CRA-2004 PABC,
 3 there were significant amounts of uncorroded steels and other Fe-base alloys in the repository
 4 throughout the 10,000-yr regulatory period. WIPP-specific experiments (Telander and
 5 Westerman 1993 and 1997) showed that steels and other Fe-based alloys will corrode by the
 6 following reactions:

11 In reducing environments, reduced iron phases (Fe(II) oxides and zero valent iron) and aqueous
 12 ferrous iron will be present. These are all reducing agents towards key actinide species (see
 13 Table SOTERM-3) and will help establish the predominance of lower-valent actinides in the
 14 WIPP. The concentration of ferrous iron could be relatively high in the WIPP brine, although its
 15 solubility has not yet been explicitly determined. There are also many potential reactions that
 16 could control and/or define the iron chemistry. The expectation is that ferrous hydroxide will
 17 control the solubility of iron, leading to a predicted solubility in the range of 10^{-6} M to 10^{-4} M for
 18 pH between 8.5 and 10.5 (Refait and Génin 1994).

19 **Table SOTERM-3. Redox Half-Reaction Potentials for Key Fe, Pb, Pu, and U Reactions at**
 20 **25 °C and I<1 (Morss, Edelstein, and Fuger 2006, Chapter 23)**

Metal Species Reduced	E_o (Acidic) in V	E_o at pH = 8 in V
$\text{Pb}^{4+} \rightarrow \text{Pb}^{2+}$	1.69	2.47
$\text{PuO}_2^+ \rightarrow \text{Pu}^{4+}$	1.170	0.70
$\text{PuO}_2^{2+} \rightarrow \text{PuO}_2^+$	0.916	0.60
$\text{Fe}(\text{OH})_3(\text{s}) \rightarrow \text{Fe}^{2+}$	Not Applicable	0.1
$\text{FeOOH}(\text{s}) \rightarrow \text{FeCO}_3(\text{s})$	Not Applicable	-0.05
$\text{UO}_2^{2+} \rightarrow \text{U}^{4+}$	0.338	-0.07
$\text{Pu}^{4+} \rightarrow \text{Pu}^{3+}$	0.982	-0.39
$\text{Pb}^{2+} \rightarrow \text{Pb}$	-0.1251	-0.54
$\text{Fe}^{3+} \rightarrow \text{Fe}^{2+}$	0.77	-0.86
$\text{Fe}(\text{II})(\text{OH})_2 \rightarrow \text{Fe}(0)$	-0.44	-0.89
$\text{U}^{4+} \rightarrow \text{U}^{3+}$	-0.607	-1.95

21
 22 Three important reactions of iron are considered for the WIPP PA. The first is the reaction of
 23 metallic iron with carbon dioxide to form strongly insoluble ferrous carbonate. The solubility
 24 product of this salt is $\log K = -10.8$ at $I = 0$ (National Institute of Standards and Technology
 25 [NIST] 2004), and it is much smaller than magnesium carbonate. This suggests that the presence

1 of iron will likely remove CO₂ from the repository more effectively than MgO due to its lower
 2 solubility product. This reaction is not included in the WIPP PA because the CO₂ reacts with
 3 MgO before the iron.

4 The second is the reaction of iron and ferrous ions with the hydrogen sulfide that could be
 5 generated in the repository by sulfate-reducing microbes. This will lead to a very insoluble
 6 ferrous sulfide precipitate with a solubility product of log K_s = -17.2 (NIST 2004). This helps
 7 remove sulfide, which can complex actinides, from brine. This reaction is assumed to occur
 8 instantaneously in the PA.

9 Finally, iron species form strong complexes with organic ligands. The strongest of these
 10 complexes is EDTA. The net effect is that dissolved iron species will compete with actinides for
 11 organic ligands, and in many cases out-compete the actinides to counteract the potential
 12 enhancement of actinide solubility that would otherwise occur. This reaction is not currently
 13 included in the PA.

14 The chemistry of iron will have a pronounced effect on WIPP-relevant actinide chemistry in
 15 many ways. The linkages of iron chemistry to the redox chemistry are well-established in the
 16 literature (Farrell et al. 1999, Fredrickson et al. 2000, Qui et al. 2001, Nakata et al. 2004, and
 17 Behrends and Van Cappellen 2005). Iron will establish reducing conditions conducive to the
 18 overall reduction of higher-valent actinide species and precipitate an iron sulfide phase that
 19 removes sulfide from solution. Additionally, iron species could sequester carbon dioxide and
 20 compete with actinides for organic and inorganic complexants, although there is no explicit
 21 credit taken for this in the WIPP PA.

22 **SOTERM-2.3.5 Chemistry of Lead in the WIPP**

23 Lead is present in the repository in the metallic form as part of the waste. The reactivity of zero-
 24 valent lead is greatly mitigated by the formation of a thin, coherent, protective oxide,
 25 oxycarbonate, chloride, or sulfate protective layer. Metallic lead also reacts slowly with water at
 26 room temperature and undergoes corrosion to form oxides and oxyhydroxides. Under slightly
 27 alkaline conditions, the hydrolysis of lead leads to formation of a poly-oxyhydroxide cation,
 28 [Pb₆O(OH)₆]⁴⁺. The following reactions are possible under WIPP-relevant conditions:

1 The solubility of lead in WIPP brine is expected to be low, due in part to the passivation process,
2 but also because of insoluble solids formation. Strong oxidants, e.g., radiolysis products, may
3 locally enhance the dissolution of lead, but alkaline brine, which contains chlorides and
4 carbonate/bicarbonate species, will overwhelm radiolytic effects to maintain a low concentration
5 of lead in the brine. In solution, lead will exist as Pb^{2+} species that are redox-active toward high-
6 valent actinides (see Table SOTERM-3) and will help establish and maintain reducing conditions
7 in the brine.

8 Lead, as was the case with iron, can influence the redox chemistry (see Table SOTERM-3) and
9 precipitate carbonate and sulfide from the WIPP brine. This leads to a redox chemistry that will
10 help maintain reducing conditions and effectively lower carbonate concentration. Both of these
11 will potentially lower actinide solubility in the WIPP. These impacts are not considered in the
12 WIPP PA.

13 **SOTERM-2.3.6 Organic Chelating Agents**

14 Organic chelating agents are used in the processing and cleanup/decontamination of actinides
15 throughout the DOE complex. For this reason, they are often present as cocontaminants with the
16 TRU component in the WIPP waste. Some of these chelating agents strongly complex actinides
17 and could have a significant effect on their solubility in brine. In this context, four organic
18 chelating agents—oxalate, acetate, citrate, and EDTA—are tracked as part of the WIPP inventory
19 process, and the potential effects of these complexants on the calculated actinide solubilities are
20 evaluated as part of the WIPP PA (Leigh et al. 2005, Brush and Xiong 2005a).

21 The potential concentrations of the key organic ligands in the WIPP were calculated a number of
22 times (Brush and Xiong 2003b, Leigh, Trone, and Fox 2005) and are based on the inventory
23 provided by Crawford and Leigh (2003). The potential concentrations of these organics used in
24 the CRA-2004 PABC were calculated by Brush and Xiong (2005a) and are based on the best
25 understanding of the WIPP inventory data available at that time. These concentrations are
26 summarized in Table SOTERM-4, where the potential maximum organic concentration in the
27 WIPP is defined as the inventory of the organic ligand divided by the minimum free volume of
28 brine needed for brine release (see Section SOTERM-2.2.4).

29 Dissolved metals will compete with the actinides to form organic complexes. As the metals in
30 the repository corrode, additional transition metal ions will dissolve into the brine. These ionic
31 species include iron (Fe) and lead (Pb). Other steel constituents, such as nickel (Ni), chromium
32 (Cr), vanadium (V), and manganese (Mn), may also be present. Additionally, divalent cations in
33 the brine, most importantly Mg^{2+} and Ca^{2+} , will also form complexes with these chelating agents
34 and compete with the actinide species. The stability constants for Mg^{2+} , Ca^{2+} , Fe^{2+} , Pb^{2+} , and
35 Ni^{2+} and deprotonation constants for the organic acids are shown in Table SOTERM-5 (National
36 Institute of Standards and Technology 2004). These formation constants, in many respects,
37 follow the same trends as the actinide species and, when present in high enough concentrations,
38 will compete with the actinide to form complexes and effectively lower the effect of organic
39 complexation on actinide solubility. However, this is not included in the PA.

1 **Table SOTERM-4. Concentrations of Organic Ligands in WIPP Brine Calculated for Use**
 2 **in the CRA-2004 PABC (Brush and Xiong 2005a)**

Organic Ligand	Compound	Inventory Amount (g)	Molecular Weight ^a (g/mol)	Potential Concentration ^c (M)	Total Potential Concentration ^c (M)
Acetate	Acetic acid	1.42×10^5	60.05	2.36×10^{-4}	1.06×10^{-2}
	Sodium acetate	8.51×10^6	82.03	1.04×10^{-2}

1 There are two final, but important, observations about the organic chelating agents present in the
2 WIPP. First, they are expected to have very different tendencies toward biodegradation, based
3 on extensive experience with soil bacteria in the literature (Banaszak, Rittmann, and Reed 1999).
4 Microbial activity, based on many general observations with soil bacteria, will likely readily
5 degrade citrate, oxalate, and acetate to very low (submicromolar) steady-state concentrations.
6 This important degradation pathway is not as certain for EDTA, which tends to resist
7 biodegradation in most groundwaters. These degradation pathways have, however, not been
8 demonstrated for the halophiles typically present in the WIPP, and it is currently assumed in the
9 WIPP PA that no degradation pathways for these organic complexants, microbiological or
10 chemical, exist.

11 The second important observation is that these chelating agents, under WIPP-relevant conditions,
12 are expected to help establish reducing conditions in the WIPP because they tend to reduce
13 higher-valent actinides. This has been demonstrated in WIPP brine for Np(V) and Pu(V/VI), but
14 was not observed for U(VI) (Reed et al. 1998). These chelating agents also tend to oxidize III
15 actinides to IV, which would have a beneficial effect on actinide solubility in the WIPP because
16 the actinides in the IV oxidation state are approximately 10 times less soluble than actinides in
17 the III oxidation state. These potentially beneficial effects of organic chelating agents on
18 actinide speciation are also currently not included in the WIPP PA.

19 **SOTERM-2.3.7 CPR in WIPP Waste**

20 The WIPP waste contains a relatively high amount of organic material, since much of the waste
21 is residue from laboratory operations where CPR materials were widely used. Current estimates
22 project over 10,000 metric tons of plastic and cellulosic materials with a much lower amount of
23 rubber material in the WIPP. This organic material is important from the perspective of
24 repository performance in that it provides an organic “feedstock” for microbial activity that
25 could lead to gas generation (carbon dioxide, hydrogen, hydrogen sulfide, and possibly
26 methane), as well as degradation products that can complex actinides or form pseudocolloids.
27 CPR degradation is represented in the PA to evaluate these potential impacts on the actinide
28 concentrations and release.

29 **SOTERM-2.4 Important Postemplacement Processes**

30 There are three important postemplacement processes that take place in the WIPP after
31 repository closure. These are metal corrosion, microbiological effects, and radiolysis. Metal
32 corrosion was already discussed as part of the iron chemistry section (Section SOTERM-2.3.4).
33 Microbiological effects and radiolysis are briefly discussed in this section.

34 **SOTERM-2.4.1 Microbial Effects in the WIPP**

35 Microbiological processes can have a significant effect on many aspects of subsurface chemical
36 and geochemical processes. This, particularly as it relates to contaminant transport and
37 remediation, has been well established for soil bacteria in low-ionic-strength and near-surface
38 groundwaters (Banaszak, Rittmann, and Reed 1998). In the WIPP, as a result of the high-ionic-
39 strength brines present, halophiles (rather than soil bacteria) will predominate. What is
40 understood about halophiles under WIPP-relevant conditions was established through a series of

1 long-term studies conducted as part of the Actinide Source Term Program (ASTP) project by
2 researchers at Brookhaven (Brush 1990; Francis and Gillow 1994; Brush 1995; Wang and Brush
3 1996a). The important and potential effects of microbial activity on the WIPP PA are also
4 discussed extensively (Leigh et al. 2005, U.S. Environmental Protection Agency 2006).

5 In the WIPP repository, many of the co-contaminants present (e.g., sulfates, phosphates,
6 organics, nitrate) are important nutrients that drive microbial activity and, in part, select the
7 primary degradation and growth pathways taken. There are WIPP-specific data which
8 demonstrate that microbial processes can occur under humid and saturated conditions in the
9 laboratory (Francis 1998). In the CRA-2004 PABC, a longer-term rate for microbial gas
10 generation was implemented based on new laboratory data obtained by the project (Leigh et al.
11 2005; Nemer and Stein 2005; Nemer, Stein, and Zelinski 2005).

12 Under repository-relevant conditions, there are primarily two important potential effects on
13 repository performance linked to the presence of microbial activity. The first is gas generation
14 due to the biodegradation of the organics present as WIPP waste (see Section SOTERM-2.3.6
15 and SOTERM-2.3.7). This is currently addressed by the WIPP PA (Nemer and Stein 2005;
16 Nemer, Stein, and Zelinski 2005). The second is the growing recognition of the linkages
17 between microbial activity and actinide speciation under microbiologically active anaerobic and
18 reducing conditions. This is not currently addressed in the WIPP PA, but adds an additional
19 argument for the sustained predominance of lower-valent actinides under WIPP-relevant
20 conditions (III and IV oxidation states).

21 **SOTERM-2.4.1.1 Gas Generation and Microbial Degradation of CPR Materials**

22 Microorganisms utilize organic compounds as the carbon source for their growth. This
23 biodegradation also provides energy to the organism because the organic compound also
24 functions as an electron donor that, when coupled with inorganic electron acceptors (oxidized
25 metals, sulfate, nitrate, and or oxygen), will provide energy to the organism. Under anaerobic
26 conditions, carbon dioxide, hydrogen, and/or methane are typically produced as gases.

27 The large quantity of CPR materials emplaced in the WIPP is the main carbon source that could
28 lead to substantial gas generation from degradation by microorganisms. As with most subsurface
29 microbial processes, there are large uncertainties surrounding the extent to which microbial
30 consumption of CPR materials can occur during the 10,000-yr WIPP regulatory period. In this
31 context, it is assumed that significant microbial consumption of CPR materials is possible, but
32 this is by no means certain.

33 To incorporate these uncertainties in the PA, the conceptual model for biodegradation used in
34 CRA-2004 (Wang and Brush 1996a and 1996b) used a probability of 0.50 for significant
35 microbial activity. This was changed in the CRA-2004 PABC calculation to be a probability of
36 1.0, meaning that microbial activity was considered in all PA vectors. The presence of this
37 microbial activity means it is assumed that microbes may consume 100% of the cellulosic
38 materials in the repository, and that there is a probability of 0.25 that microbes may consume the
39 plastic and rubber materials. Thus, there is microbial consumption of cellulosic materials, but
40 not of plastic or rubber materials, in 75% of the PA realizations (vectors), and microbial
41 consumption of all CPR materials in 25% of the vectors.

1 Microbial consumption of CPR materials could affect the actinide source term in four ways:

- 2 1. Production of significant quantities of CO₂, which could acidify the brine in the absence of
- 3 an MgO buffer or increase the solubility of actinides by carbonate complexation at the
- 4 expected mildly alkaline pH
- 5 2. Bioreduction of higher-valent actinide species leading to lower-valent, less-soluble actinide
- 6 species
- 7 3. Degradation of solubilizing organic ligands, leading to lower actinide solubility
- 8 4. Production of humic and microbial colloids that could increase the amount of actinide
- 9 pseudocolloids in the brine

10 The effect of CO₂ production is discussed in this section. The remaining three effects are
 11 implicitly considered in the analyses that address the oxidation-state distributions (Section
 12 SOTERM-4.2), the effects of organic ligands (Section SOTERM-2.3.6), and the effects of
 13 colloids (Section SOTERM-3.8). The simplifications used in the PA calculations for all four of
 14 these effects are discussed at the end of this section.

15 Microbial activity, if it occurs to a significant extent in the WIPP, would consume CPR materials
 16 by the following sequential reactions (Brush 1990, Francis and Gillow 1994, Brush 1995, Wang
 17 and Brush 1996a, and Francis 1998):

21 Methanogenesis, described by Reaction (SOTERM.20), is not included as a degradation pathway
 22 in CRA-2004 PABC (Leigh et al. 2005) due to uncertainty about the availability of sulfate (see
 23 Section SOTERM-2.2.5) in the DRZ and its exclusion is a conservative assumption relative to
 24 the amount of carbon dioxide that could be produced. In effect, the CRA-2004 PABC and this
 25 PA assume that an excess of sulfate is always available to sustain sulfate-reduction
 26 biodegradation pathways. When unlimited sulfate is available from natural sources in the host
 27 rock, which is the assumption for the CRA-2004 PABC and for this PA, 4% of the gas
 28 generation occurs through denitrification and 96% occurs by way of sulfate reduction (Leigh et
 29 al. 2005, Section 2.4).

30 Microbial consumption of CPR materials, therefore, could produce significant quantities of CO₂,
 31 which could in turn acidify any brine present in the repository and increase the solubilities of the
 32 actinides relative to those predicted for neutral and mildly basic conditions. Therefore, the DOE
 33 is emplacing MgO in the repository to decrease actinide solubilities by consuming essentially all
 34 of the CO₂ that could be produced by microbial consumption of CPR materials, and by buffering
 35 (controlling) the f_{CO₂} and pH within ranges that are favorable from the standpoint of actinide
 36 speciation and solubility (see Section SOTERM-2.3.2).

1 Three effects of microbial consumption of CPR materials are recognized in the system
 2 performance modeling. A simplification has been made so the effects will be time-independent
 3 after 100 years. These effects are

- 4 1. CO₂ production. With the addition of excess MgO, the effects of CO₂ production are
 5 minimized, and it is assumed that the system may be modeled using the brucite-
 6 hydromagnesite (Mg₅(CO₃)₄(OH)₂·4H₂O) buffer.
- 7 2. Redox effects. After 100 years, the repository will have a reducing environment. This is, in
 8 part, established by the postclosure microbial consumption of oxygen, but is also due to the
 9 corrosion of steel. This combined effect leads to the formation of an anoxic reducing
 10 environment in the WIPP.
- 11 3. Production of humic and microbial colloids is possible/probable and likely to be the main
 12 colloidal contributor to actinide concentrations in DBR release.

13 **SOTERM-2.4.1.2 Bioreduction of Multivalent Actinides**

14 The bioreduction of higher-valent actinides is an important potential effect of microbial activity
 15 in the WIPP. This potential effect is beneficial to the WIPP licensing case since it strengthens
 16 the current PA assumption that lower-valent, and therefore less-soluble, actinide species will
 17 predominate in the WIPP. The bioreduction of actinides has recently been the focus of much
 18 research due to its expected role in microbially-mediated remediation and containment of
 19 subsurface contaminants (Banaszak, Rittman, and Reed 1998; Banaszak et al. 1999; Lloyd,
 20 Young, and Macaskie 2000; Reed et al. 2007; Icopini, Boukhalfa, and Neu 2007; and Francis,
 21 Dodge, and Gillow 2008). The extent that this applies to the halophiles typically present in the
 22 WIPP is, however, uncertain, although it is expected that similar trends in bioreduction will be
 23 observed.

24 The linkage between actinide oxidation state and microbiological processes for soil bacteria is
 25 shown in Figure SOTERM-2. Under anaerobic conditions, U(VI), Pu(V/VI), and Np(V) are
 26 reduced for a wide range of microbes and electron donors. U(VI) and Np(V) species are
 27 primarily reduced enzymatically by reductases formed. The end product in both of these cases is
 28 the actinide in the IV oxidation state. The Pu system, however, is more complex in that there are
 29 strongly coupled abiotic and biotic pathways (see Table SOTERM-3) and the formation of
 30 Pu(III), rather than Pu(IV), is sometimes observed when Pu(IV) solubilization mechanisms
 31 coexist.

32 Although there is a reasonable expectation that bioreduction of higher-valent actinides will occur
 33 for microbiologically active anaerobic systems in the WIPP, WIPP-specific data that support this
 34 expectation have not been obtained. For this reason, the potential effects of bioreduction on
 35 multivalent actinide systems are not considered in the WIPP PA.

8 SOTERM-2.4.2 Radiolysis Effects in the WIPP

9 Radiolysis effects in the WIPP are caused by the interaction of ionizing radiation and particles
10 (neutrons, α , β , and γ) with the gases, brines, and materials present in the repository. These
11 effects have not been extensively studied under WIPP-related conditions, but there is a fairly
12 good general understanding of their extent and nature. The strongly reducing and oxidizing
13 transients generated radiolytically in aqueous systems can affect the oxidation state distribution
14 of multivalent metals and actinides. In high-ionic-strength sodium chloride brines, this is
15 primarily exhibited in the oxidation of Am(III) and Pu(III/IV) species to Am(V) and Pu(V/VI).
16 Additionally, the radiolytic breakdown of water leads to the formation of molecular hydrogen,
17 which adds to gas generation in the WIPP after brine inundation. Lastly, radiolytic effects can
18 affect the stability and/or enhance the degradation of waste components (e.g., CPR degradation,
19 iron/metal corrosion, and initial actinide oxidation state distribution) during the unsaturated and
20 saturated phases in repository history.

21 The effects of radiolysis for most conditions expected in the WIPP are predicted to be transient
22 and insignificant. In this context, there is a recognition that although radiolysis can lead to
23 localized conditions and effects that could oxidize multivalent actinides, the brine chemistry,
24 metal corrosion, and microbiological activity will combine to very rapidly overwhelm these
25 effects. For this reason, radiolysis effects on actinide solubility are not explicitly included in the
26 WIPP PA to calculate actinide concentrations. More specifics on the overall mechanisms, brine

1 radiation chemistry, and potential radiolytic effects on actinide speciation are given in this
2 section.

3 **SOTERM-2.4.2.1 Radiation Chemistry of Brine Systems**

4 The radiolysis of high-ionic-strength brine systems has not been extensively studied, but some
5 studies exist (Büppelman, Kim, and Lierse 1988; Kim et al. 1994; Kelm, Pashalidis, and Kim
6 1999; Ershov et al. 2002). The many components in the brine systems of interest to the WIPP
7 will lead to a relatively complex radiation chemistry and the formation of numerous transients
8 and free radicals.

9 In contrast to this, the radiation chemistry of pure and dilute aqueous systems has been
10 extensively investigated, and detailed reviews of this research have been published (Draganic
11 and Draganic 1971, Spinks and Woods 1990). The irradiation of pure water leads to the
12 formation of molecular hydrogen peroxide (H_2O_2) and hydrogen (H_2). These molecular yields
13 are relatively insensitive to a wide range of conditions in dilute systems for a given type of
14 ionizing radiation. Molecular yields are $G_{\text{H}_2} = 0.45$ molecule (molec)/100 electron-volt (eV) and
15 $G_{\text{H}_2\text{O}_2} = 0.7$ molec/100 eV for low Linear Energy Transfer (LET) ionizing radiation (β , and γ)
16 and $G_{\text{H}_2} = 1.6$ molec/100 eV and $G_{\text{H}_2\text{O}_2} = 1.5$ molec/100 eV for high LET radiation (α and
17 neutrons). The radiolytic formation of hydrogen in the WIPP brine due to self-irradiation effects
18 of ^{239}Pu was established and a molecular yield of $G_{\text{H}_2} = 1.4$ molec/100 eV was measured (Reed
19 et al. 1993). This yield is consistent with the high LET literature, even though the irradiations
20 were performed in brine.

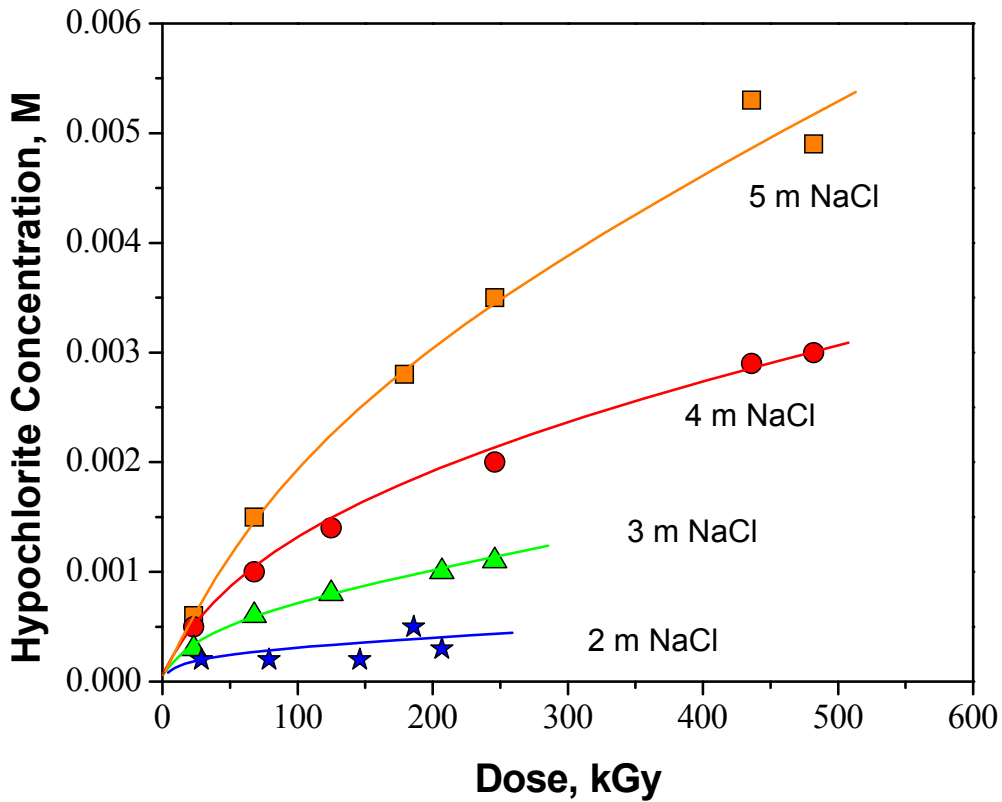

21 The high concentrations of electron and free radical scavengers present in the WIPP brine have a
22 pronounced effect on the radiation chemistry. Most importantly, halides react with the hydroxyl
23 radical ($\text{OH}\cdot$) or act as scavengers (such as Cl^- or Br^-) to gradually lower the molecular yield of
24 H_2O_2 as the concentration of the scavengers is increasing (Kelm, Pashalidis, and Kim 1999). In
25 this context, oxidizing transient species are “chemically” stored as oxychlorides and
26 oxybromides, leading to a shift towards more oxidizing conditions. Figure SOTERM-3 gives an
27 overview of the radiolytic pathways and mechanisms that are likely (Buppelmann, Kim, and
28 Lierse 1988). In NaCl brine, the formation of chloride species (ClO^- , HOCl , Cl_2 , and Cl_3^-) is
29 favored, instead of H_2O_2 (Büppelmann, Kim, and Lierse 1988).

30 Kelm, Pashalidis, and Kim (1999) showed that the formation of hypochlorite ion increases with
31 the chloride concentration and the dose (Figure SOTERM-4) in NaCl brine. The authors found
32 that in solutions containing 37 gigabecquerel (GBq)/liter (L) of ^{238}Pu , the hypochlorite
33 concentration increases with time (dose) and appears to approach a steady state (see Figure
34 SOTERM-4). At a constant dose rate, the maximum hypochlorite concentration depends on the
35 chloride concentration. It was also observed that hypochlorite ion generation was negligible
36 when chloride concentrations were smaller than 2 M.

37 In the WIPP brine, however, some solutes other than chloride may play a role. Ershov et al.
38 (2002) showed that small amounts of bromide in natural brines under radiolysis can give Cl_2^- ,
39 ClBr^- , and Br^- radical anions at the radical step, and then mixed halogen molecules and trihalide
40 ions by radical recombination at the molecular step (Ershov et al. 2002). The hydrolysis of
41

7 **Figure SOTERM-4. Radiolytic Formation of Hypochlorite Ion in Solutions of Various**
8 **NaCl Concentrations at a Constant Alpha Activity of 37 GBq/L at**
9 **pH~12 (Based on Data in Kelm, Pashalidis, and Kim 1999)**

1 mixed halogen molecules can then result in the formation of hypobromite (OBr^-) (acidic form:
2 hypobromous acid [HOBr]), a starting substance to more stable bromates of higher oxidation
3 state (Ershov et al. 2002).

4 Some WIPP-specific experiments were performed to establish the key radiolytic product in
5 GWB and ERDA-6 brine (Lucchini et al. 2009). This study confirms that hydrogen peroxide
6 (H_2O_2) and hypochlorite ion (OCl^-) are unstable in these WIPP brines, due in part to metallic
7 impurities in the brine. There was, however, an accelerated decomposition of these species when
8 bromide (Br^-) was present, which is the case for both ERDA-6 and GWB brines. Here, OCl^-
9 readily and stoichiometricly reacted with Br^- to form hypobromite ion (OBr^-), which appeared to
10 be the most important radiolytic transient observed under these conditions. OBr^- , like OCl^- , is
11 also an oxidizing species ($E^\circ=0.76\text{V}$), that will likely lead to the oxidation of multivalent
12 actinides in the WIPP, but this reactivity has not been established experimentally under
13 representative WIPP conditions (Lucchini et al. 2009).

14 In the WIPP, most of the brine radiolysis is caused by the deposition of alpha particles from the
15 TRU isotopes present in the WIPP waste. The range (distance traveled until the alpha particle's
16 energy is lost) of these alpha particles is very short (<40 microns) and radiolysis of the brine
17 solution will take place at the solid-liquid interface. Locally, the concentration of oxidative
18 radiolytic products of brine, such as hypochlorite, chlorite, chlorate, and products of their
19 reaction with brine components (e.g., hypobromite) may be high, and they may directly interact
20 with the radioactive surface. These "very-near" radiolytic effects, however, are expected to be
21 quickly mitigated by the bulk brine chemistry and the reaction of reducing agents (e.g., reduced
22 iron) with the oxidizing molecular products formed.

23 **SOTERM-2.4.2.2 Potential Radiolytic Effects on Actinide Speciation and Solubility**

24 A buildup of oxidizing radiolytic products in brine may increase the redox potential of the brine
25 (Büppelmann, Kim, and Lierse 1988), and consequently directly generate higher-valent actinide
26 species. Alternatively, these radiolytic products could be inserted into some solid actinide
27 phases. For example, Kim et al. (1994) studied the solubility of schoepite, $(\text{UO}_2)(\text{OH})_2 \cdot x\text{H}_2\text{O}$,
28 with hypochlorite ion in 0.1M NaCl at 25 °C (77 °F), in CO_2 -free atmosphere (Kim et al. 1994).
29 Their X-Ray Diffraction (XRD) patterns of the residual precipitates showed the introduction of
30 hypochlorite ion in precipitates. Kim et al. (1994) observed that the presence of hypochlorite ion
31 in the initial schoepite structure enhanced the solubility of the solid 10 to 100 times in the range
32 of pH 6.0-9.8, compared with its solubility in the absence of hypochlorite ion (Kim et al. 1994).
33 However, this effect was reduced when the molar ratio $[\text{ClO}^-]/[\text{UO}_2^{2+}]$ increased. This scenario
34 is unlikely to occur in the WIPP because the potential buildup of oxidizing radiolytic products
35 generated in brine is readily overwhelmed by the overall reducing capacity of the site (reduced
36 metals and microbial processes).

37 The buildup of oxidizing radiolytic products due to brine radiolysis has also been shown to
38 significantly affect the solution chemistry of Am. For example, Am(III) was oxidized to the
39 more soluble forms of Am, namely AmO_2^+ and AmO_2^{2+} (Magirius, Carnall, and Kim 1985; Katz,
40 Seaborg, and Morss 1986; Stadler and Kim 1988; and Meyer et al. 2002). Magirius, Carnall, and
41 Kim (1985) reported on the radiation effects exerted upon a 5 M NaCl solution at the pH 8 to 9
42 range using precipitated $\text{Am}(\text{OH})_3$ at a concentration of 1.03×10^{-3} M (1.07 curie [Ci]/L). They

1 observed that the precipitate began to show discoloration, changing from pink Am^{3+} to brown
2 AmO_2^+ , within 24 hours (h), with quantitative oxidation of all the Am to AmO_2^+ within 1 week.
3 Because Pu is more readily oxidized than Am, the expectation is that Pu could also be oxidized
4 in irradiated brine. The metastability of Pu(VI) in the WIPP brine when no reducing agents were
5 present was established and attributed to self-radiolysis effects of the ^{239}Pu isotope used (Reed,
6 Okajima, and Richmann 1994; Reed et al. 2006).

7 Stadler and Kim (1988) also report the existence of higher oxidation states of Am, due to self
8 radiolysis. Solubility experiments on $\text{Am}(\text{OH})_3(\text{solid}[s])$ in 3 M NaCl resulted in much higher
9 Am concentrations than was calculated from the solubility product. This difference was assigned
10 to the radiolytic oxidation of Am^{3+} to AmO_2^+ . Spectrophotometric evidence of AmO_2^+ species in
11 solution was reported. The authors report the value of $\log_{10}K_{S,0} = -9.3 \pm 0.5$ for the reaction

13 The solubility product of $\text{AmO}_2\text{OH}(s)$ is in general agreement with other solubility studies on
14 different pentavalent actinides.

15 These results show there is clearly a potential for oxidized, higher-valent actinides to form in
16 brine when no reducing agents are present. This, however, needs to be interpreted in the context
17 of the strong reducing agents and processes that will predominate in the WIPP, such as
18 bioreduction (Section SOTERM-2.4.1.2), iron reduction (Section SOTERM-3.4.2), and
19 reduction by organic complexants (Section SOTERM-2.3.4). WIPP-specific data show that the
20 presence of reduced iron (Fe(II/0)) leads to a rapid reduction of Pu(VI) to Pu(IV) species under a
21 wide range of anoxic conditions (Reed et al. 2006, Reed et al. 2009). These results are expected
22 to extend to the Am(V) system, since this species is more readily reduced than Pu(V/VI).
23 Reduced iron will also react with radiolytically generated oxidizing species, such as hypochlorite
24 or hypobromite, to prevent their buildup in the brine solution with time. In summary, these
25 WIPP-specific results show that the reductants present in WIPP waste (reduced metals and
26 organics) will overwhelm potential radiolytic effects under the expected conditions in the WIPP,
27 and a significant and sustained radiolytic enhancement of actinide solubilities is not predicted.

28 **SOTERM-2.5 Changes in WIPP Conditions since the CRA-2004 and the** 29 **CRA-2004 PABC**

30 There are no significant changes in the WIPP repository conditions, chemistry, and processes
31 since the CRA-2004 and the last PA performed (Leigh et al. 2005). Specifically, the
32 assumptions and parameters given in Table SOTERM-1 are the same as those used for the CRA-
33 2004 PABC. This applies to all the discussions in Section SOTERM-2.1, Section SOTERM-2.2,
34 Section SOTERM-2.3, and Section SOTERM-2.4.

35 Three WIPP-relevant processes were reviewed and updated. First, actinide reduction is a direct
36 consequence of microbial activity under anoxic conditions (see Section SOTERM-2.4.1). This,
37 in fact, strengthens the current PA position that reducing conditions will be maintained in the
38 WIPP, although this is not accounted for in PA. Second, there is an increased understanding of
39 the effects of ionizing radiation on actinide speciation in sodium chloride brine systems (Section
40 SOTERM-2.4.2). This leads to recognition of the role of hypobromite in WIPP-specific brines.

1 Additionally, WIPP-specific data show that the effects of radiolysis, which can create locally
2 more oxidizing zones in the repository, are readily overwhelmed by the effects of reduced iron.
3 Third, further progress was made in understanding the reaction sequence and interactions of
4 MgO in WIPP-relevant brine systems (see Section SOTERM-2.3.3).

5 The TRU inventory was updated. This update impacted the concentration of organic chelating
6 agents (see Section SOTERM-2.3.6), the volume of the TRU waste inventory, and the amount of
7 emplaced materials which increased the CPR inventory (see Section SOTERM-2.3.7).

8 It is important to note that the CRA-2004 PABC included changes to the CRA-2004 PA in
9 response to comments received from the EPA (Cotsworth 2005). These are discussed in detail as
10 part of the CRA-2004 PABC documentation (Leigh et al. 2005). The specific changes for CRA-
11 2004 PABC that revised or clarified the microbial assumptions and input are as follows:

- 12 1. Gas generation rates were revised to account for slower, longer-term processes based on new
13 WIPP-specific data (Nemer and Stein 2005; Nemer, Stein, and Zelinski 2005a).
- 14 2. All PA vectors are now assumed to be microbial (this was changed from a probability of 0.5
15 in CRA-2004 PA).
- 16 3. Gas generation is assumed to occur only through denitrification (~4%) and sulfate reduction
17 (~96%). It is assumed that methanogenesis does not occur because sulfate is assumed to be
18 always available for microbial processes.

1 **SOTERM-3.0 WIPP-Relevant Actinide Chemistry**

2 The speciation of actinides under WIPP-relevant conditions defines the source term for actinide
3 release from the WIPP in release scenarios where dissolved actinide concentrations are important
4 (e.g., DBR and transport through the Salado or Culebra). The key factors that establish the
5 concentrations of dissolved actinides under subsurface conditions are known. The most
6 important of these factors for the WIPP repository are listed below.

- 7 1. Actinide redox chemistry is a critical factor in establishing the concentration of actinides in
8 brine. The solubility of reduced actinides (III and IV oxidation states) is significantly lower
9 than oxidized forms (V and/or VI). In this context, maintaining reducing conditions in the
10 WIPP and the strong coupling of the chemistry for reduced metals and microbiological
11 processes with actinides are important.
- 12 2. The complexation of each actinide species is a critical factor in defining its solubility. For a
13 given oxidation state, the inorganic and organic complexes present will define the solubility
14 of the actinide. These complexants are in the preemplacement environment, are part of the
15 TRU waste that is emplaced, or are produced as a result of subsurface processes, most
16 notably microbial and corrosion processes.
- 17 3. Intrinsic and pseudoactinide colloid formation is a critical factor in defining the overall
18 solution concentration of each actinide. The contribution of actinide colloids to the
19 concentration of actinides in the WIPP is predicted to be significant. Many of the key TRU
20 species in their expected oxidation states tend to form colloids or strongly associate with
21 nonactinide colloids present (e.g., microbial, humic and organic).

22 The WIPP PA approach as established in the initial WIPP license application (U.S. Department
23 of Energy 1996) and continued through the most recent PA calculations (Leigh et al. 2005)
24 accounts for all three of these key factors.

25 The PA concept of actinide speciation in the WIPP is well grounded in what has been observed
26 for actinide contaminants in near-surface groundwater. In natural systems, the following
27 inorganic ligands are potentially important complexants of radionuclides in solution:
28 $\text{CO}_3^{2-}/\text{HCO}_3^-$, OH^- , Cl^- , $\text{SO}_4^{2-}/\text{S}^{2-}$, fluoride (F^-), and phosphate. Additionally, anthropogenic and
29 bioderived chelating agents can strongly bind actinide species and will compete with the
30 inorganic complexants present. Lastly, the tendencies of actinides to form intrinsic colloids and
31 strongly associate or bind with colloidal particles are also well established. The relative
32 importance of these complexants and processes depends on the pH, radionuclide oxidation state
33 present, the presence of other metals, and the relative ligand concentrations. There are a number
34 of general reviews on various aspects of actinide environmental chemistry (Allard 1982;
35 Choppin, Liljenzin, and Rydberg 2004 [pp. 94–112]; Clark, Hobart, and Neu 1995; Banaszak,
36 Rittmann, and Reed 1998; Runde 2000; Nitsche et al. 1992).

37 For the anoxic, reducing, and mildly basic brine systems expected in the WIPP (see Table
38 SOTERM-1), the most important inorganic complexants are expected to be
39 carbonate/bicarbonate and hydroxide. There are also important organic complexants that coexist
40 in TRU waste with the potential to strongly influence actinide solubility. In this context, the

1 relative importance of actinides and overall oxidation state, based on the CRA-2004 PABC TRU
2 waste inventory, with respect to the potential release of actinides from the WIPP, is:

3 **Actinides:** Pu \approx Am \gg U $>$ Th \gg Np \approx Cm (SOTERM.22)

4
5 **Actinide Oxidation State:** An(III) $>$ An(IV) \gg An(VI) \gg An(V) (SOTERM.23)

6
7 In the CRA-2004 PABC (Leigh et al. 2005), the contribution of Pu, Am, U, Th, Cm, and Np is
8 expressly considered, although only Pu and Am contribute significantly to TRU release from the
9 WIPP. The III oxidation state is the most important oxidation state based on current WIPP PA
10 assumptions because Am always exists in the III state, Pu exists in the III state in 50% of the
11 vectors, and the III oxidation state is more soluble than the IV (see Section SOTERM-4.0 for a
12 more detailed discussion).

13 In this section, an update of the literature and a summary of new WIPP-specific data is provided
14 (when available) for all the actinides that contribute in one way or another to the PA. Section
15 SOTERM-3.1 gives an overview of the projected and current inventory of actinides in the WIPP;
16 Section SOTERM-3.2, Section SOTERM-3.3, Section SOTERM-3.4, Section SOTERM-3.5, and
17 Section SOTERM-3.6 contain an overview of the relevant environmental chemistry and WIPP-
18 specific results for Th, U, Np, Pu, and Am/Cm, respectively; Section SOTERM-3.7 pertains to
19 the complexation of actinides by organic chelating agents in the WIPP; Section SOTERM-3.8
20 provides an overview of the potential for the formation of actinide colloids in the WIPP; and
21 Section SOTERM-3.9 is a summary of changes since the CRA-2004 and CRA-2004 PABC. An
22 up-front overview of these sections appears in Table SOTERM-6. The PA implementation of
23 this actinide environmental chemistry is discussed in Section SOTERM-4.0 and Section
24 SOTERM-5.0.

25 **SOTERM-3.1 Actinide Inventory in the WIPP**

26 The actinide inventory for the WIPP, based on the Transuranic Waste Baseline Inventory Report-
27 2004 inventory (U.S. Department of Energy 2006), is given in Table SOTERM-7. This is also
28 the inventory used to calculate the CRA-2004 PABC (Brush and Xiong 2005b) actinide
29 solubilities. Also included in this table are the calculated inventory limits of the various
30 actinides and radionuclides considered by the WIPP PA.

31 Over long time frames, only Pu and Am are expected to make a significant contribution to
32 releases from the WIPP. Curium (Cm), which is predominantly present as ^{244}Cm , is a factor of
33 10 below the calculated solubility for III actinides when fully dissolved and, with its very short
34 half-life (18.11 years), will not be important beyond the 100-year period of institutional control.
35 Although relatively large inventories of cesium (Cs) and strontium (Sr) are projected, these can
36 only contribute significantly to the overall release from the WIPP for the first 100 years of
37 repository history, so are not significant beyond the period of institutional control.

38 Table SOTERM-8 gives the panel-specific inventory of the actinides for Panels 1 and 2 in the
39 WIPP. These data are based on characterization of containers in Panels 1 and 2 WIPP Waste
40 Information System (WWIS). Also included in this inventory is the amount of key waste
41

1 **Table SOTERM-6. Overview of the WIPP PA View/Role and Relevant Environmental**
 2 **Chemistry of the Key Actinide Species in the WIPP (References for**
 3 **Each Actinide are Provided in the Following Sections)**

Actinide	WIPP PA View/Role	Environmental Chemistry
Thorium	Not a TRU component. Currently included in PA calculations, but not a significant contributor to actinide release. Used as an oxidation-state invariant analog for the IV actinides. Th data are used in Fracture-Matrix Transport (FMT) to calculate the solubility of Pu(IV), Np(IV), and U(IV).	Exists as Th^{4+} complexes and is sparingly soluble under a wide range of environmental conditions.
Uranium	Not a TRU component. Potentially useful as a VI analog for Pu(VI) species. Currently, U is conservatively assumed to be U(VI) in 50% of the PA vectors (set at a 1 mM solubility) and U(IV) in 50% of the PA vectors.	Exists as UO_2^{2+} and U^{4+} species that are strongly correlated with redox conditions. Can form highly insoluble U(VI) and U(IV) phases. Can persist up to mM concentrations in near-surface groundwater.
Neptunium	TRU component. Currently included in PABC calculations, but not a significant contributor to actinide release. Assumed to be IV in 50% of the PA vectors and V in 50% of the PA vectors. Expected to be in the IV oxidation state under the conditions expected in the WIPP.	Mobile and relatively soluble as the NpO_2^+ species under oxidizing conditions. Is fairly insoluble and immobile as Np^{4+} under reducing conditions.
Plutonium	TRU component. Major contributor to actinide release calculations. Assumed to be IV in 50% of PA vectors and III in the other 50% of PA vectors.	Relatively immobile and insoluble as a subsurface contaminant. Persists as Pu^{4+} except under biomediated, strongly reducing conditions where transitory Pu^{3+} species may be formed. Expected to be transported primarily through colloidal mechanisms.
Americium	TRU component. Major contributor to actinide release calculations. Exists in the III oxidation state in all vectors and its thermodynamic data is used by FMT for all III oxidation state calculations. Significant colloidal contribution due to strong association as a pseudocolloid.	Relatively immobile and insoluble as a subsurface contaminant. Persists as Am^{3+} complexes under a wide range of environmental conditions.
Curium	Small quantities of ^{243}Cm , ^{245}Cm , and ^{248}Cm are present in the WIPP. ^{244}Cm , although present, is not a TRU waste component due to its <20 year half-life. These are very minor contributors to actinide release. Chemistry is analogous to Am(III).	Not a very significant concern as a subsurface contaminant. Has the same chemistry as Am, so it will persist as a Cm^{3+} species.
Organic Chelating Agents	The effects of EDTA, citrate, oxalate, and acetate on actinide solubility are considered in WIPP PA. These are present in WIPP waste and it is assumed that they are neither destroyed nor created by WIPP-relevant subsurface processes.	EDTA can persist under a wide range of environmental conditions and strongly chelates actinides. Citrate, oxalate, and acetate will likely be degraded due to microbial activity.
Actinide Colloids	Pseudocolloids with actinides are formed. These are accounted for in WIPP PA and add to the conservatism of the actinide concentrations calculated.	Importance and role of An colloid-facilitated transport are the subject of much ongoing debate. Although colloids are formed, it is not clear that they lead to increased actinide migration.

Radionuclides	Amount in kg (Ci)	Materials	Amount (kg)
²⁴¹ Am	9.2 (3.2 × 10 ⁴)	Iron-based metal alloys	4,922,035
Pu (total)	1,405	Aluminum-based metal alloys	17,730
²³⁹ Pu	1,306 (8.1 × 10 ⁴)	Other metal alloys	121,526
U (total)	6,850	MgO	6,667,625
²³⁸ U	6,808 (2.3)	Cellulosics	477,213
²³⁷ Np	1.2 (0.85)	Plastic	876,399

4
 5 components emplaced. From the perspective of actinide solubility and PA, the most important of
 6 these are MgO and iron. Over 8,000 metric tons of iron is already emplaced, contrasting with the
 7 much smaller amounts of TRU present (1.8 kg of Np, 43.6 kg of Am, and 3.8 metric tons of Pu).
 8 Approximately 11,000 metric tons of MgO are present. These data support and are consistent
 9 with current WIPP PA assumptions that sufficient MgO and an overwhelming amount of iron
 10 will be present in the WIPP to establish strongly reducing conditions and favorable carbonate
 11 levels.

12 **SOTERM-3.2 Thorium Chemistry**

13 Th is not a TRU component. An estimated 31 metric tons of Th will be in the WIPP. The
 14 release of Th as the ²³⁰Th isotope was calculated in the CRA-2004 PABC and does not
 15 significantly contribute to the overall release of activity from the WIPP. Th is, however,
 16 important for the WIPP in that it is used as a redox-invariant analog for the IV actinides (Pu(IV),
 17 Np(IV), and U(IV)), and Th complexation data is used in the FMT code for the An(IV) solubility
 18 calculations (see Section SOTERM-4.4.3).

19 **SOTERM-3.2.1 Thorium Environmental Chemistry**

20 Th, under a wide range of conditions, has one stable oxidation state in aqueous solutions: the
 21 Th⁴⁺ tetravalent ion. For this reason, the environmental chemistry of Th is understood from the

1 perspective of the solubility and complexation of this species, which is also the species expected
2 to be present in the WIPP environment when DBR and transport release scenarios are important.

3 Other oxidation states for Th in aqueous systems have been reported. Recent data by Klapötke
4 and Schulz (1997) that suggests a Th^{3+} species as a somewhat stable species in slightly acidic
5 solution is not correct; it has been discounted because the proposed reaction for the species'
6 formation is shown to be thermodynamically impossible, and the azido-chloro Th^{4+} complex is
7 incorrectly assigned to the Th^{3+} species (Ionova, Madic, and Guillaumont 1998).

8 The hydrolysis of Th^{4+} , as is true for all An(IV) species in the WIPP, is complex and a critically
9 important interaction in defining the overall solubility of Th. This was recently investigated by
10 Ekberg et al. (2000), Rai et al. (2000), Moulin et al. (2001), and Okamoto, Mochizuki, and
11 Tsushim (2003) and critically reviewed by Neck and Kim (2001) and Moriyama et al. (2005).
12 The authors have proposed a comprehensive set of thermodynamic constants that extends to all
13 tetravalent actinides. The solubility products were determined for amorphous (am) $\text{Th}(\text{OH})_4$
14 (Neck et al. 2002, Altmaier et al. 2005; Altmaier et al. 2006) and for crystalline ThO_2 (Neck et
15 al. 2003), as well as for specific ion interaction theory parameters (Neck, Altmaier, and
16 Fanghänel 2006). The thermodynamic stability constants are listed in Table SOTERM-9.

17 **Table SOTERM-9. Thermodynamic Stability Constants for Key Th Hydrolytic Species**

Hydrolytic Reaction/Species	Stability Constant
Mononuclear Species	
$\text{Th}(\text{OH})_{4, \text{am}} \rightleftharpoons \text{Th}^{4+} + 4\text{OH}^-$	$\log K_{s, \text{am}} = -47.8 \pm 0.3$
$\text{Th}(\text{OH})_{4, \text{cr}} \rightleftharpoons \text{Th}^{4+} + 4\text{OH}^-$	$\log K_{s, \text{cr}} = -53.2 \pm 0.4$
$\text{Th}^{4+} + \text{OH}^- \rightleftharpoons \text{Th}(\text{OH})^{3+}$	$\log \beta^0_1 = 11.8 \pm 0.2$
$\text{Th}^{4+} + 2\text{OH}^- \rightleftharpoons \text{Th}(\text{OH})_2^{2+}$	$\log \beta^0_2 = 22.0 \pm 0.6$
$\text{Th}^{4+} + 3\text{OH}^- \rightleftharpoons \text{Th}(\text{OH})_3^+$	$\log \beta^0_3 = 31 \pm 1$
$\text{Th}^{4+} + 4\text{OH}^- \rightleftharpoons \text{Th}(\text{OH})_{4, \text{aq}}$	$\log \beta^0_4 = 38.5 \pm 1$
Polynuclear Species	
$4\text{Th}^{4+} + 12\text{OH}^- \rightleftharpoons \text{Th}_4(\text{OH})_{12}^{4+}$	$\log \beta^0_{4,12} = 141$
$6\text{Th}^{4+} + 15\text{OH}^- \rightleftharpoons \text{Th}_6(\text{OH})_{15}^{9+}$	$\log \beta^0_{6,15} = 176$

18

19 The presence of carbonate in solution greatly increases the solubility of thorium dioxide (ThO_2).
20 An increase by one order of magnitude of the carbonate concentration in the range of 0.1 – 2 M
21 leads to a five-order-of-magnitude increase in the Th(IV) solubility due to the formation of
22 mono- and penta-carbonate complexes. Östhols, Bruno, and Grenthe (1994) proposed the
23 following equilibrium reactions and the corresponding stability constants:

26 This speciation scheme, however, has been criticized in recent work (Altmaier et al. 2005)
27 because it overpredicts the dependency of Th solubility on carbonate and underpredicts the effect

1 of hydrolysis at higher pH. That hydrolysis prevails at $\text{pH} > 10$ is supported by relatively detailed
2 experimental results (see Figure SOTERM-5). These data are explained by the predominance in
3 this system of $\text{Th}(\text{OH})(\text{CO}_3)_4^{5-}$ complex rather than $\text{Th}(\text{CO}_3)_5^{6-}$. A greater role for other ternary
4 complexes of thorium (e.g. $\text{Th}(\text{OH})_2(\text{CO}_3)_2^{2-}$), which are also likely to be present in the WIPP
5 conditions, is also proposed, and formation constants for these complexation reactions are
6 reported. The use of the pentacarbonyl complex for the IV actinides in the WIPP PA, for these
7 reasons, is a conservative assumption that overpredicts the solubility of the IV oxidation state at
8 $\text{pH} > 10$. A correction in the FMT database to the value of the $\text{Th}(\text{OH})_4(\text{aqueous [aq]})$ to be
9 consistent with Neck et al. (2002) was incorporated into the CRA-2004 PABC.

10 Oxyanions such as phosphate and, to a lesser extent, sulfate, also form Th^{4+} complexes that can
11 precipitate at $\text{pH} < 5$. The effect of phosphate on solubility of microcrystalline ThO_2 is very
12 limited. The stability constants for $\text{Th}^{4+}/\text{H}_2\text{PO}_4^-$ and $\text{Th}^{4+}/\text{HPO}_4^{2-}$ were reported (Langmuir and
13 Herman 1980). Overall, the role of these oxyanions is expected to be unimportant for the mildly
14 basic brines ($\text{pH} \sim 8-10$) present in the WIPP.

15 A new perturbation to the understanding of Th speciation, as well as other actinides in the IV
16 oxidation state, is the recent observation that Ca, and to a lesser extent, magnesium (Mg),
17 enhances Th solubility at $\text{pH} > 10$ when carbonate is present. In recent publications, the
18 formation of $\text{Ca}_4[\text{Th}(\text{OH})_8]^{4+}$ and $\text{Ca}_4[\text{Pu}(\text{OH})_8]^{4+}$ ion pairs in alkaline CaCl_2 solution is reported
19 (Brendebach et al. 2007; Altmaier, Neck, and Fanghänel 2007). These species cause a rapid
20 increase in the solubility of all tetravalent actinides at pH greater than 11. This increased
21 solubility is only observed at CaCl_2 concentrations above 0.5 M for Th(IV), and correspondingly
22 above 2 M for Pu(IV) species. This effect can be discounted for the WIPP PA because Ca
23 concentrations in the WIPP are predicted to be approximately 14 mM or less with a pH of
24 approximately 8.7. These are both well below the levels needed to see a significant effect for
25 both Th and Pu.

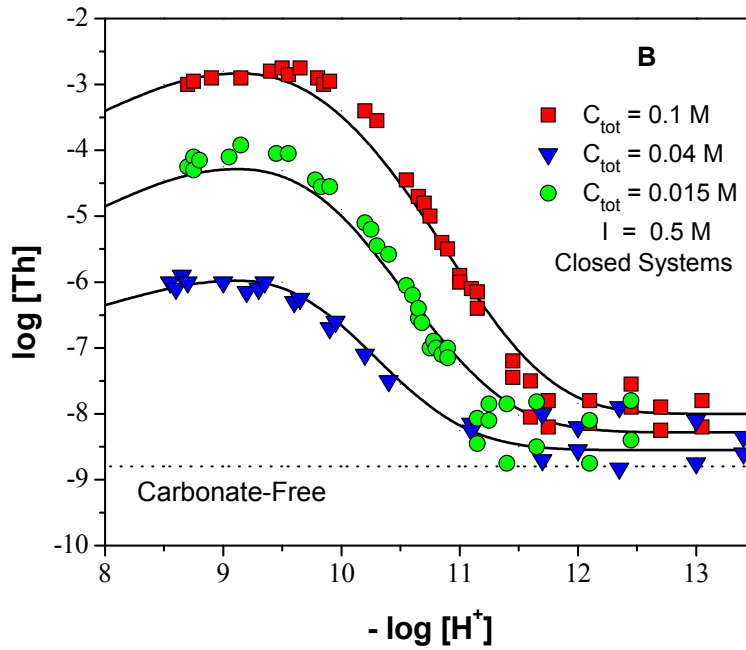

26 Actinides in the IV oxidation state, because of the complexity of their solution chemistry and
27 very high tendency towards hydrolysis, form colloidal species in groundwater. The potential
28 effect of colloid formation on solubility of Th(IV) in concentrated NaCl and MgCl_2 solution was
29 recently published by Altmaier, Neck, and Fanghänel (2004) and is shown in Figure SOTERM-
30 6. In neutral-to-alkaline solutions, colloids could be formed as Th oxyhydroxide with \log
31 $[\text{Th}]_{(\text{colloid [coll]})} = -6.3 \pm 0.5$, independent of ionic strength. In Mg solutions, the formation of
32 pseudocolloids (i.e., Th(IV)) sorbed onto $\text{Mg}_2(\text{OH})_3\text{Cl} \cdot 4\text{H}_2\text{O}(\text{coll})$ led to an apparent increase of
33 the total Th concentration up to 10^{-5} M (Walther 2003, Degueldre and Kline 2007, Bundschuh et
34 al. 2000). For these reasons, colloid formation is addressed in the WIPP PA.

35 **SOTERM-3.2.2 WIPP-Specific Results since the CRA-2004 and the CRA-** 36 **2004 PABC**

37 There were no new WIPP-specific data on Th solubility and speciation obtained since CRA-
38 2004. There were, however, a number of WIPP-relevant experiments reported in simplified
39 brine systems, mainly by researchers at Karlsruhe. These results were summarized above in the
40 context of their relationship to the environmental chemistry of Th in high-ionic-strength systems.
41 These solubility data support the current WIPP PA assumptions on An(IV) solubility and extend
42

7 past project data to a broader range of pH and carbonate levels. These results also note that Ca-
8 enhanced carbonate complexation, something that has only been understood in the last couple of
9 years, can greatly increase the solubility of IV actinides. This complexation, however, requires
10 relatively high pH in combination with very high Ca levels, something that is not expected in the
11 WIPP. The expected pH and dissolved Ca levels predict little or no effect due to this complex.

12 **SOTERM-3.3 Uranium Chemistry**

13 U is not a TRU component, but is, by mass, expected to be the most prevalent actinide
14 component in the WIPP. Current estimates predict that ~647 metric tons will be placed in the
15 repository (see Table SOTERM-8). By mass, greater than 99% of this U will be the ²³⁸U isotope,
16 with minor amounts of ²³³U, ²³⁴U, ²³⁵U, and ²³⁶U. U does not contribute significantly to the
17 calculation of actinide release through cuttings/cavings and spillings because of its low specific
18 activity. U release can occur through the Culebra in very small amounts because of its
19 potentially high solubility in the VI oxidation state.

1 U release, as the ^{234}U isotope, was calculated in the CRA-2004 PABC. In the WIPP PA, the
 2 oxidation state distribution assumption is that U speciates as U(IV) in 50% of the PA vectors and
 3 as U(VI) in the other 50% of the vectors. The U concentration for this oxidation state is
 4 currently set at 1 mM (U.S. Environmental Protection Agency 2005), since there is no An(VI)
 5 model in the WIPP. U(IV) solubility is calculated using the Th(IV) speciation data reported in
 6 the FMT model. For the current WIPP PA assumptions, uranium does not contribute
 7 significantly to the overall release of actinides from the WIPP.

8 SOTERM-3.3.1 Uranium Environmental Chemistry

9 U is by far the most studied of the actinides under environmentally relevant conditions. An
 10 extensive review of this chemistry, as it relates to the WIPP case, was completed (Lucchini et al
 11 2009) and more general reviews can be found (Morss, Edelstein, and Fuger 2006, Guillaumont et
 12 al. 2003). An overview of U environmental chemistry is presented in this section.

13 SOTERM-3.3.1.1 Uranium Subsurface Redox Chemistry

14 U can theoretically exist in aqueous solution in the III, IV, V, and VI oxidation states (Hobart
 15 1990; Keller 1971 [pp. 195–215]; Clark, Hobart, and Neu 1995). In the environment, however,
 16 only the IV and VI oxidation states, which exist as U^{4+} and UO_2^{2+} species, are present. U^{3+} ,
 17 should it be formed, is metastable and readily oxidized in aqueous solution, and U(V) only exists
 18 as a very short-lived transient that instantaneously disproportionates to form U(IV) and U(VI)
 19 species. The corresponding reduction potential diagram for U at pH = 0, 8, and 14 is given in
 20 Figure SOTERM-7 (Morss, Edelstein, and Fuger 2006).

22 **Figure SOTERM-7. Reduction Potential Diagram for U at pH = 0, 8, and 14 (Based on**
 23 **Data in Morss, Edelstein, and Fuger 2006). For the Expected**
 24 **Reducing and Mildly Basic pH Conditions in the WIPP, U(IV) is**
 25 **Predicted to be the Predominant Oxidation State.**

26 Under oxidizing subsurface conditions typical of most near-surface groundwaters, U(VI) as
 27 UO_2^{2+} uranyl complexes, is the predominant oxidation state and is not easily reduced
 28 geochemically. Thermodynamically, uranyl species are stable even under mildly reducing

1 conditions and are not reduced by some Fe(II) phases (see Table SOTERM-3). In anoxic WIPP
2 brine experiments with a hydrogen overpressure, uranyl persists as a stable hydrolytic or
3 carbonate complex for over two years (Reed and Wygmans 1997).

4 In the anoxic and strongly reducing environment expected in the WIPP, however, potential
5 reduction pathways exist. The two most important of these reduction pathways are reaction of
6 uranyl with reduced iron phases (Fe[0/II]), and bioreduction through enzymatic pathways by
7 anaerobic microbes, such as metal reducers, sulfate reducers, and methanogens (see Figure
8 SOTERM-2). For these reasons, U(IV) is the oxidation state expected to predominate in the
9 WIPP when brine inundation occurs.

10 The use of iron barriers in the removal of uranyl from groundwater is well established and has
11 been reported for the removal of U(VI) from groundwater using zero-valent iron barriers (Gu et
12 al. 1998, Fiedor et al. 1998, Farrell et al. 1999) and iron corrosion products formed in saline
13 solution (Grambow et al. 1996). However, in those studies, it was unclear whether the removal
14 of uranyl (UO_2^{2+}) resulted from reductive precipitation or from adsorption onto the iron
15 corrosion products (Gu et al. 1998). In their experiments under saline conditions, Grambow et
16 al. (1996) found that a large percentage of U was rapidly adsorbed onto the iron corrosion
17 products consisting of over 97% hydrous Fe(II) oxide, and very little U(IV) was found. The
18 complexity of the U-Fe-H₂O-CO₂ system explains the scarcity of the experimental data and the
19 lack of a predominant mechanism (reduction-precipitation or adsorption) for the removal of
20 U(VI) in the presence of iron.

21 Under anoxic conditions, Trolard et al. (1997) establishes that the corrosion of steel and iron
22 generates Fe(II)/Fe(III) hydroxide species known as green rusts. Green rusts contain a certain
23 amount of nonhydroxyl anions (carbonate, halides, or sulfate); they have a high specific surface
24 area (Cui and Spahiu 2002) and a high cation sequestration capacity (O'Loughlin et al. 2003).
25 They are considered metastable oxidation products of Fe(II) to magnetite Fe₃O₄ and Fe(III)
26 oxyhydroxides (e.g., goethite $\alpha\text{-FeOOH}$) (O'Loughlin et al. 2003). A few experimental studies
27 demonstrate that U(VI) is reduced to U(IV) by green rusts (Dodge et al. 2002, O'Loughlin et al.
28 2003). The formation of a UO₂ phase was measured by Extended X-Ray Absorption Fine
29 Structure (EXAFS) analysis (O'Loughlin et al. 2003) or by X-Ray Absorption Near Edge
30 Structure (XANES) analysis and confirmed by X-ray Photoelectron Spectroscopy and Fourier
31 Transform Infrared Spectroscopy (FTIR) (Dodge et al. 2002).

32 Banaszak, Rittman, and Reed (1998) have reviewed the important role of microbial processes in
33 the reduction of multivalent metals under anaerobic/reducing conditions. For uranyl in particular,
34 several studies exist that show that U(VI) is reduced to U(IV) species under a wide range of
35 conditions (Lovley et al. 1991, Lovley et al. 1993, Barton et al. 1996, Huang et al. 1998,
36 Abdelouas et al. 2000, Bender et al. 2000, Fredrickson et al. 2000). Most of this work pertains to
37 groundwater bacteria, and is not directly applicable to the WIPP.

38 There are relatively few studies that investigate the interaction of U with the halophiles that are
39 more typically present in WIPP brine. Some WIPP-relevant research was done (Francis et al.
40 2000), but this work was mostly focused on gas generation, not actinide interactions. It remains
41 to be demonstrated that the mechanisms leading to the bioreduction of U(VI) also extend to the
42 microbes present in the WIPP, although it is fully expected that this will be the case.

1 SOTERM-3.3.1.2 Solubility of U(IV)

2 Tetravalent U is expected to be the dominant oxidation state in the WIPP as a result of the
3 reducing conditions that will prevail. The solubility of U(IV) under these conditions is
4 analogous to that observed for Th (see Section SOTERM-3.2 and discussion in Section
5 SOTERM-4.1) and is, in fact, calculated in the WIPP PA with the Th(IV) database.

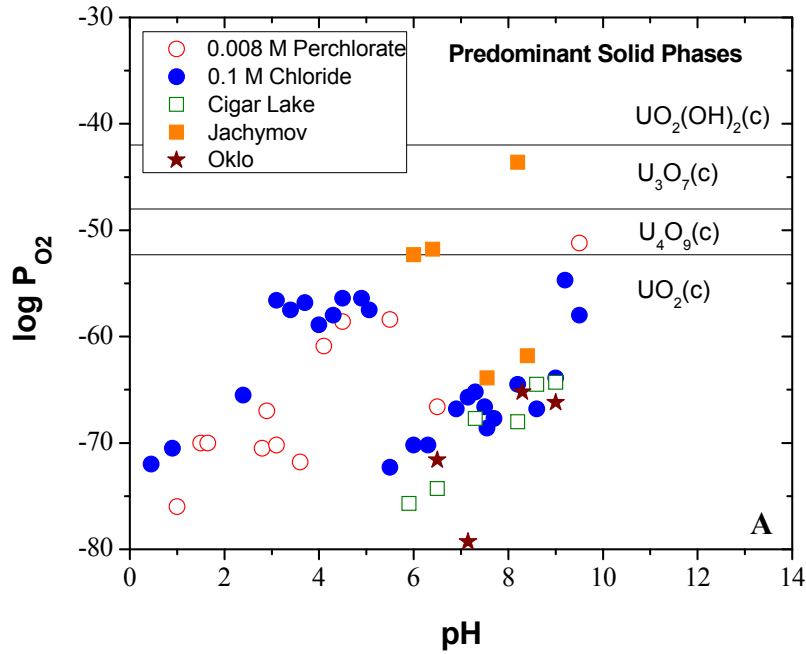

6 Under strictly reducing conditions, such as those expected in the WIPP, the most common and
7 stable U solid is U dioxide (UO₂, uraninite) and associated hydrates. The aqueous species that
8 predominates between pH 5-10, at low carbonate concentration, is the neutral tetra-hydroxide
9 complex. This is described by the following equation:

12 The solubilities reported in the literature for hydrous UO₂·xH₂O(s), amorphous (am) UO₂, or
13 microcrystalline UO₂ are very scattered (Neck and Kim 2001). The explanation in the NEA
14 review on U speciation (Guillaumont et al. 2003) is that the solubility data reported do not
15 correspond to a unique material, but rather to a range of U oxide solids that have different
16 thermodynamic stabilities. The species predominance diagrams for U are shown in Figure
17 SOTERM-8 for aqueous and solid phases (Casas et al. 1998), based on the thermodynamic
18 constants given for U at 25 °C by Guillaumont et al. (2003).

19 Experimentally, U⁴⁺ is readily oxidized to UO₂²⁺. This occurs even when only trace levels of
20 oxygen, which are often below the limit of detection by most laboratory instrumentation, exist.
21 This explains why there are relatively few studies of U⁴⁺. It is also problematic because there are
22 very large discrepancies in the literature as a result of experimental artifact. In particular, there
23 are a number of published results (Rai, Felmy, and Ryan 1990, Gayer and Leider 1957, Ryan and
24 Rai 1983, Tremain et al. 1981, Casas et al. 1998) that suggest amphotericity for U⁴⁺ at pH >10.
25 This, however, likely resulted from combined effects of two experimental artifacts: (1) oxidation
26 to UO₂²⁺, which is much more soluble, and (2) the presence of carbonate, which is a strong
27 complexant of U⁴⁺.

28 The solubility of U(IV) phases were also determined in simplified brines under conditions that
29 relate to the WIPP (Rai et al. 1997, Rai et al. 1998; Yajima, Kawamura, and Ueta 1995, Torero
30 et al. 1994). These data are shown in Figure SOTERM-9. Rai et al. (1997) determine the
31 solubility of freshly precipitated UO₂·xH₂O(am) in NaCl and MgCl₂ solutions of various ionic
32 strengths. They estimate the concentration of U(OH)₄(aq) in equilibrium with UO₂·xH₂O(am) to
33 be about 10^{-8.0} M, and a number of data with greater concentrations in the neutral and alkaline
34 range are ascribed to the presence of U(VI) in solution. This is in fair agreement with the value
35 of 10^{-(8.7±0.4)} M proposed by Yajima, Kawamura, and Ueta (1995). It is important to note that
36 U(IV) concentrations at pH >5 show no significant dependence on the initial solid phase (Figure
37 SOTERM-9); both fresh precipitates in oversaturation experiments or electrodeposited
38 microcrystalline UO₂(s) in undersaturation experiments gave the same results (Torrero et al.
39 1994).

 8 **is Calculated With the Model Proposed by Rai et al. (1997).**

9 **SOTERM-3.3.1.3 Solubility and Speciation of U(VI)**

10 U(VI) phases and aqueous species, although not expected to predominate in the WIPP, could be
 11 present due to the localized effects of radiolysis (see Section SOTERM-2.4.2). The WIPP PA
 12 currently makes the conservative assumption that U(VI) species predominate in 50% of the PA
 13 vectors. The solubility of U(VI) is, however, not explicitly calculated in WIPP PA, since there is
 14 no model for actinides in the VI oxidation state. The potential contribution of U(VI) species to
 15 the overall solubility of U in the WIPP is implicitly considered in the WIPP PA in the 1 mM
 16 value for U solubility (U.S. Environmental Protection Agency 2005). Prior to this, the solubility
 17 of U was defined as 1.2×10^{-5} M based on an assessment of the literature and existing WIPP-
 18 relevant experimental data by Hobart and Moore (1996).

19 The role of carbonate (CO_3^{2-}) in the U(VI) solubility is indeed important (Clark, Hobart, and Neu
 20 1995, Guillaumont et al. 2003). In the absence of competing complexing ligands, carbonate
 21 complexation will dominate the speciation of the uranyl ion under near-neutral pH conditions as
 22 long as there is ample carbonate-bicarbonate available. Complexation constants for binary
 23 U(VI) carbonate complexes at $I = 0$ M and 25 °C (77 °F) are listed in Table SOTERM-10

24

$\text{UO}_2\text{CO}_3(\text{cr}) \rightleftharpoons \text{UO}_2^{2+} + \text{CO}_3^{2-}$	$\text{Log } K_{\text{SP}(\text{cr})}^0 = -14.76 \pm 0.02$
Reactions and Formation Constants β_{nq}^0 for $(\text{UO}_2)_n(\text{CO}_3)_q^{2n-2q}$	
$\text{UO}_2^{2+} + \text{CO}_3^{2-} \rightleftharpoons \text{UO}_2\text{CO}_3(\text{aq})$	$\text{Log } \beta_{11}^0 = 9.94 \pm 0.03$
$\text{UO}_2^{2+} + 2 \text{CO}_3^{2-} \rightleftharpoons \text{UO}_2(\text{CO}_3)_2^{2-}$	$\text{Log } \beta_{12}^0 = 16.61 \pm 0.09$
$\text{UO}_2^{2+} + 3 \text{CO}_3^{2-} \rightleftharpoons \text{UO}_2(\text{CO}_3)_3^{4-}$	$\text{Log } \beta_{13}^0 = 21.84 \pm 0.04$
$3 \text{UO}_2^{2+} + 6 \text{CO}_3^{2-} \rightleftharpoons (\text{UO}_2)_3(\text{CO}_3)_6^{6-}$	$\text{Log } \beta_{36}^0 = 55.6 \pm 0.5$

3
 4 (Guillaumont et al. 2003). The three monomeric complexes of general formula $\text{UO}_2(\text{CO}_3)$,
 5 $\text{UO}_2(\text{CO}_3)_2^{2-}$, and $\text{UO}_2(\text{CO}_3)_3^{4-}$ are present under the appropriate conditions. There is also
 6 evidence from electrochemical, solubility, and spectroscopy data that support the existence of
 7 $(\text{UO}_2)_3(\text{CO}_3)_6^{6-}$, $(\text{UO}_2)_2(\text{CO}_3)(\text{OH})_3^-$, and $(\text{UO}_2)_{11}(\text{CO}_3)_6(\text{OH})_{12}^{2-}$ polynuclear species, which can
 8 only form under the conditions of high-metal-ion concentration or high ionic strength (Clark,
 9 Hobart, and Neu 1995). At uranyl concentrations above 10^{-3} M, the trimeric cluster
 10 $(\text{UO}_2)_3(\text{CO}_3)_6^{6-}$ can also be present in significant concentrations. When the uranyl ion
 11 concentration begins to exceed the carbonate concentration, hydrolysis will play an increasingly
 12 important role (Clark, Hobart, and Neu 1995).

13 It is generally accepted that the major complex in solution at high carbonate concentrations is
 14 $\text{UO}_2(\text{CO}_3)_3^{4-}$ (Kramer-Schnabel et al. 1992, Peper et al. 2004). However, at $I = 0.5$ M and $I = 3$
 15 M, the polynuclear $(\text{UO}_2)_3(\text{CO}_3)_6^{6-}$ species becomes an important competitor of $\text{UO}_2(\text{CO}_3)_3^{4-}$.
 16 Grenthe et al. (1984) indicated that the formation of $(\text{UO}_2)_3(\text{CO}_3)_6^{6-}$ is favored at high ionic
 17 strengths as a result of possible stabilization of the complex by ions of the background
 18 electrolyte.

19 The solubility of U(VI) in the WIPP is defined by the combined contribution of two processes:
 20 hydrolysis with oxyhydroxide phase formation, and carbonate complexation with U carbonate
 21 phase formation. These are both very complex systems, and there are many proposed speciation
 22 schemes. In carbonate-free or low-carbonate solutions, the speciation of U(VI) is dominated by
 23 hydrolysis.

24 The solubility of uranyl carbonate UO_2CO_3 and the formation constants for the associated
 25 complexes were determined at 25 °C (77 °F) in 0.1M NaClO_4 by Kramer-Schnabel et al. (1992).
 26 The authors noticed a change in the composition of the solid when the pH increased above 6.5.
 27 Using ^{14}C -labeled carbonate and X-ray analysis, they observed that UO_2CO_3 changed to a mixed
 28 uranyl-hydroxy-carbonate at $\text{pH} > 6.5$ and to uranyl hydroxide or sodium diuranate at $\text{pH} > 8$.
 29 The different transition states were not characterized in detail. In an earlier investigation, the
 30 existence of hydroxycarbonato uranyl species in the neutral pH range at 25 °C was also
 31 determined. An important observation from these studies is that the U concentration in solutions
 32 decreases with increasing ionic strength when UO_2CO_3 is the major aqueous U species.

1 At high pH, Yamamura et al. (1998) demonstrate that hydrolysis overwhelms carbonate
2 complexation. The solubility of U(VI) was measured in highly basic solutions ($11 \leq \text{pH} \leq 14$) at
3 an ionic strength of $I = 0.5 - 2 \text{ M}$ over a wide range of carbonate concentrations ($10^{-3} - 0.5 \text{ M}$)
4 using both oversaturation and undersaturation approaches. In the oversaturation experiments, the
5 solubility of U(VI) decreased with increasing equilibration time from one week to one year and
6 was explained as an increase in the crystallinity of the solid phase with aging. The solid phase
7 was identified as $\text{Na}_2\text{U}_2\text{O}_7 \cdot x\text{H}_2\text{O}$ by XRD. The undersaturation experiments conducted for one
8 month with the solid phase indicated a rapid equilibrium. These data were interpreted by
9 considering the formation of $\text{UO}_2(\text{OH})_3^-$, $\text{UO}_2(\text{OH})_4^{2-}$, and $\text{UO}_2(\text{CO}_3)_3^{4-}$ (Yamamura et al. 1998).

10 The influence of carbonate on U(VI) solubility in highly saline solutions was investigated by Lin
11 et al. (1998) and Fanghänel and Neck (2002). Lin et al. (1998) evaluated U(VI) solubilities with
12 up to 5 M NaCl in a range of carbonate concentrations. At carbonate-ion concentrations greater
13 than 10^{-7} M , $\text{UO}_2(\text{CO}_3)_3^{4-}$ was the dominant U(VI) complex in solution. At higher CO_2 partial
14 pressures, the solubility-controlling solid phase was found to be $\text{UO}_2\text{CO}_3(\text{s})$, whereas at lower
15 partial pressures, sodium uranate was identified as the solid phase in NaCl -saturated solutions.
16 This study, although interesting, is of questionable use to the WIPP because the details were not
17 fully published.

18 The solubility-controlling U(VI) solid phases are schoepite-type phases $\text{UO}_3 \cdot x\text{H}_2\text{O}(\text{s})$. This was
19 reported by Sandino and Grambow (1994) as corrosion products of spent fuel in long-term
20 leaching experiments under oxidizing conditions. However, in complex systems where many
21 other elements are present, the uranyl hydroxides are not predicted to predominate in the long
22 term. Specifically, they undergo a transformation into different phases that can include divalent
23 cations (e.g., Ca^{2+} , Pb^{2+} , Ba^{2+}) and monovalent cations, such as K^+ or Na^+ (Sandino and
24 Grambow 1994). The transformation reaction is generally dependent on pH and groundwater
25 composition. As an example, Fanghänel and Neck (2002) observed the formation of a sodium
26 (Na) uranate phase [clarkeite, $\text{NaUO}_2\text{O}(\text{OH}) \cdot \text{H}_2\text{O}$] in 5 M NaCl experiments at pH 8. The extent
27 to which these alkali uranate salts contribute to U solubility in the higher-complexity brines
28 expected in the WIPP is not clear.

29 The U solid phases formed in the presence of carbonate were also investigated. Meinrath and
30 Kimura studied solid-liquid equilibria of U(VI) at 100, 0.98 and 0.03% CO_2 partial pressures in
31 the pH range 2.8-4.6 in 0.1 M NaClO_4 solution at $(24 \pm 2) \text{ }^\circ\text{C}$ (Meinrath and Kimura 1993). The
32 solid phase formed under 100% CO_2 partial pressure was found as a faint, yellow-greenish
33 powder. It was identified by XRD as rutherfordine (UO_2CO_3). At 0.98 and 0.03% CO_2 partial
34 pressures, the solids generated were bright yellow, and identified by XRD as schoepite
35 ($\text{UO}_3 \cdot 2\text{H}_2\text{O}$). The authors established that the phase transition between these two phases
36 (rutherfordine and schoepite) occurs at a CO_2 partial pressure of 2.8% (Meinrath and Kimura
37 1993). This estimated value is in agreement with the experimental results of Grenthe et al.
38 (1984) who report rutherfordine as a solubility-limiting solid phase at partial pressures $\geq 4.8\%$
39 CO_2 .

1 **SOTERM-3.3.2 WIPP-Specific Results since the CRA-2004 and the CRA-**
 2 **2004 PABC**

3 The solubility of U(VI) in the absence of carbonate was extensively studied since CRA-2004 in
 4 simulated GWB and ERDA-6 brine (Lucchini et al. 2009). An overview of these results is
 5 shown in Figure SOTERM-10, and a comparison of these results with other solubility data in the
 6 literature is given in Table SOTERM-11. The measured U(VI) solubilities were about 10^{-6} M in
 7 GWB brine at $pC_{H^+} \geq 7$ and about 10^{-8} - 10^{-7} M in ERDA-6 at $pC_{H^+} \geq 8$. These results put an
 8 upper bound of $\sim 10^{-5}$ M for the solubility of uranyl in the carbonate-free WIPP brines for the
 9 investigated range of experimental conditions. At the expected pC_{H^+} in the WIPP (~ 8.7), the
 10 measured uranium solubility was between 10^{-7} M and 10^{-6} M.

2

3 The most important observations from these U(VI) solubility studies were

- 4 • The measured solubility of U(VI) in the absence of carbonate was ~10 – 100 times lower than
5 those reported by others in the literature and well below the current 1 mM limit used in the
6 WIPP PA (which applies to all conditions, including carbonate). These lower solubilities
7 reflect the lack of oxygen and carbonate in the brine systems investigated.
- 8 • U(VI) solubility does not exhibit amphoteric behavior.

- 1 • A difference in U(VI) solubility between the two brines investigated was noted, with U
2 concentrations in GWB ~10 times higher at pH > 8. This is caused by the complexation of
3 U(VI) with the higher borate and sulfate concentrations in GWB.

4 The new WIPP-specific data do not address the more important issue of the effects of carbonate
5 complexation on U(VI) solubility, but they do establish a baseline to determine this effect.

6 **SOTERM-3.4 Neptunium Chemistry**

7 The WIPP repository is projected to contain ~10 kg of Np, primarily as the ²³⁷Np isotope (see
8 Table SOTERM-8). Its inventory increases with time from the decay of ²⁴¹Am and the
9 possibility of ²³⁸U (n, 2n) reactions, but this increase is projected to be less than a factor of two
10 during the regulatory period of the WIPP. In the WIPP PA, Np speciates as Np(IV) in 50% of
11 the PA vectors and as Np(V) in the other 50% of the PA vectors. The contribution of Np to
12 actinide release from the WIPP was included in the CRA-2004 PABC (Brush and Xiong 2005a;
13 Leigh et al. 2005) calculation, but its effect on release was negligible. Arguments have also been
14 made that it should be excluded from consideration in the WIPP PA based on its low inventory
15 (Brush and Garner 2005).

16 **SOTERM-3.4.1 Neptunium Environmental Chemistry**

17 The environmental chemistry of Np is somewhat unique in the actinide series as a result of the
18 relatively high stability of the NpO₂⁺ species, which is in the V oxidation state, under a wide
19 range of conditions typically found in the subsurface. This oxidation state is prevalent when
20 oxidizing conditions predominate (Hobart 1990). It is mobile because it has a relatively high
21 solubility and it is not strongly sorbed or complexed. It does not hydrolyze strongly, with little
22 or no measurable hydrolysis until pH >7 (Neck, Kim, and Kanellakopoulos 1992; Itagaki et al.
23 1992). Much of the complexation data for inorganic and organic complexes for Np pertains to
24 the V oxidation state for this reason (Lemire et al. 2001). The log K_{sp} for NpO₂OH (s) is 4.5 ±
25 0.06 (Neck, Kim, and Kanellakopoulos 1992).

26 Np can, however, actually exist in up to five oxidation states in aqueous media. The redox
27 potentials under basic conditions are (Marinot and Fuger 1985):

31 Only the Np(IV) and Np(VI) oxidation states, in addition to Np(V), can exist under the right
32 conditions in reducing or oxidizing groundwater (Hobart 1990; Keller 1971 [pp. 195–215];
33 Clark, Hobart, and Neu 1995). These exist as Np⁴⁺ complexes and NpO₂²⁺ complexes. Np(VI),
34 unlike Np(V), is strongly hydrolyzed at near-neutral pH and is readily reduced by many
35 constituents typically found in groundwater (e.g., organics and most reduced metals). For these
36 reasons, it does not tend to persist in groundwater under most conditions.

37 Under reducing anoxic conditions, Np⁴⁺ species can predominate. These Np⁴⁺ species readily
38 undergo hydrolysis and are comparable to Pu⁴⁺ in this regard. This system is highly irreversible

1 and probably polymeric in nature, as is observed for Pu⁴⁺. The measured solubility of Np⁴⁺ is
2 10^{-8.5} to 10^{-8.1} M with Np(OH)₄, not Np(OH)₅⁻, as the predominant aqueous species (Rai and
3 Ryan 1985, and Eriksen et al. 1993). The importance and predominance of the Np(IV) oxidation
4 state in reducing conditions is even more pronounced when anaerobic bacteria are present.
5 Np(V) was readily reduced by sulfate-reducing bacteria (Banaszak, Reed, and Rittmann 1998)
6 and methanogenic consortia (Banaszak et al. 1999), and precipitated as Np(IV) solids.

7 In WIPP-specific experiments, Reed and Wygmans (1997) found spectroscopic evidence for
8 reduction of Np(VI) to Np(V) in ERDA-6 (Castile) brine at pH 10, and have observed complete
9 reduction of Np(VI) to Np(V) in G-Seep (Salado) brine at pH 7 when no iron or microbial
10 activity were present. In the presence of oxalate, citrate, and EDTA, Reed and Wygmans (1997)
11 have observed rapid and complete reduction of Np(VI) to Np(V) coupled with a slower
12 formation of Np(IV) species. The stability of Np(V) under these conditions is further confirmed
13 by Neck, Runde, and Kim (1995), who showed that Np(V) carbonate complexes are stable in 5M
14 NaCl.

15 In the expected WIPP environment, however, where anoxic and reducing conditions with
16 microbial activity and reduced iron are expected to be present, Np(IV) is expected to be the
17 predominant oxidation state (Rai and Ryan 1985, Rai, Strickert, and McVay 1982a, Kim et al.
18 1985, Pryke and Rees 1986). This is based on studies of the solubility of NpO₂OH in 1 M and
19 5 M NaCl solutions at pH 6.5 where the reduction of Np(V) to Np(IV) was observed (Kim et al.
20 1985, Neck, Kim, and Kanellakopoulos 1992).

21 **SOTERM-3.4.2 WIPP-Specific Results since the CRA-2004 and the CRA-** 22 **2004 PABC**

23 There are no new WIPP-relevant results on the chemistry and speciation of Np since CRA-2004
24 and the CRA-2004 PABC.

25 **SOTERM-3.5 Plutonium Chemistry**

26 Pu is a key TRU component that contributes significantly to the potential for TRU release from
27 the WIPP under all release mechanisms considered by PA. Pu isotopes, estimated to be ~10
28 metric tons at the time of closure, represent approximately 89% of the Ci content for actinides in
29 TRU waste (see Table SOTERM-7). There are five isotopes of Pu that make a significant
30 contribution to the Pu inventory, but ²³⁹Pu, ²³⁸Pu, and ²⁴¹Pu are the major contributors to the Ci
31 content. Under the conditions expected in the WIPP, Pu(IV) is expected to be the predominant
32 oxidation state (Weiner 1996). A more extensive review of Pu subsurface speciation issues as
33 they pertain to the WIPP case was completed (Reed et al. 2009).

34 In the WIPP PA, all of the Pu is assumed to be reduced and present in the III or IV oxidation
35 state. Half of the PA vectors contain 100% Pu(III), with the other half of the vectors containing
36 100% Pu(IV) species. Because the solubility of Pu(III) is roughly 10 times higher, the
37 assumption that it is present is a conservatism built into the WIPP PA. The two higher-valent Pu
38 oxidation states, Pu(V) and Pu(VI), are not considered in the PA because they cannot persist
39 under the expected reducing and anoxic conditions in the WIPP.

1 SOTERM-3.5.1 Plutonium Environmental Chemistry

2 Generally, Pu can exist in oxidation states III, IV, V, VI, and VII (Katz, Seaborg, and Morss
3 1986, p. 781). Of these, only Pu(V), Pu(IV), and Pu(III) are expected to be important under
4 environmentally relevant oxidizing and reducing conditions. Pu(VII) is very unstable and exists
5 only in extremely basic solutions (for example, 7 M NaOH) that are not expected in the WIPP.
6 Pu(VI) can persist in the WIPP in the absence of reductants, but is readily reduced in the
7 presence of Fe(II/0) species, reduced by many organic chelators (Reed et al. 1998), and reduced
8 in anaerobic, biologically active systems (Reed et al. 2007; Icopini, Boukhalfa, and Neu 2007).
9 The reduction of Pu(VI), under WIPP-relevant conditions, was shown by Clark and Tait (1996),
10 Reed and Wygmans (1997), and Reed et al. (2007).

11 SOTERM-3.5.1.1 Importance of Redox for Plutonium Speciation

12 The role and importance of redox reactions in determining actinide mobility and solubility are
13 beyond question (Van Luik et al. 1987; Allard 1982; Choppin and Rao 1992). The redox
14 potentials for the various oxidation states at pH 7 are (Cleveland 1979, pp. 11–46)

19 A typical phase diagram for Pu in groundwater that illustrates the importance of redox is shown
20 in Figure SOTERM-11.

21 Higher-valent Pu, specifically Pu(V) and Pu(VI), can be present in near-surface oxidizing
22 groundwaters (Orlandini, Penrose, and Nelson 1986). The association of Pu(V) with organic
23 colloidal material was proposed as the mechanism by which subsurface migration occurred.
24 Pu(VI), in near-neutral systems, is strongly and irreversibly hydrolyzed (Okajima and Reed
25 1993). It is also readily reduced by organics and reduced metal species even when oxygen is
26 present to form Pu(V), and is not generally stable under most groundwater-relevant conditions.

27 Pu(V), by analogy with Np(V), does not undergo hydrolysis until $\text{pH} > 7$ and tends to form weak
28 complexes. It readily disproportionates to form Pu(IV) and Pu(VI) at high concentrations and is
29 relatively easy to reduce in the environment under anoxic conditions. $\text{Fe}^{2+}(\text{aq})$, Fe(II) minerals,
30 and metallic iron reduce Pu(V) to Pu(IV).

31 In geochemical systems, redox control is often interpreted in terms of the iron, and in a broader
32 sense, reduced metal, mineralogy, and associated aqueous chemistry (Sanchez, Murray, and
33 Sibley 1985, White, Yee, and Flexser 1985). In the WIPP case, iron will undergo anoxic
34 corrosion, producing Fe^{2+} . Both metallic iron (Fe^0) and Fe^{2+} have been shown to quantitatively
35 reduce Pu(VI) in the WIPP brines to either Pu(IV) or Pu(III). Clark and Tait (1996) and Felmy
36 et al. (1996) have experimentally observed the reduction of Pu(VI) carbonates by either Fe^0 or
37 Fe^{2+} to Pu(IV). In the absence of carbonates, a quantitative reduction of Pu(VI) is also observed,
38 but the oxidation state of the resulting species cannot be definitively determined because its
39

7 **Hydrolytic Species with Lesser Contributions From Carbonate.**

8 concentration is below the lower detection limit of the oxidation state analytical process (about
9 10^{-9} M). However, since this concentration is well below the expected solubility of Pu(V)
10 species, it was reasonably assumed that the Pu must have been reduced to either the IV or III
11 oxidation state. Neretnieks (1982) has shown that when dissolved actinides in moving
12 groundwater came in contact with Fe(II), the actinides were reduced to a much-less-soluble
13 oxidation state and precipitated.

14 Pu(III) is not predicted to be stable under the expected WIPP conditions. There are some
15 mechanisms, however, identified in which Pu(III) species can be formed. Felmy et al. (1989)
16 observed some Pu(III) in the WIPP brines at neutral and slightly basic conditions. PA
17 conservatively takes account of these minor mechanisms by assuming that Pu is speciated as
18 Pu(III) in 50% of the PA vectors.

19 **SOTERM-3.5.1.2 Bioreduction of Higher-Valent Plutonium**

20 Comprehensive and critical reviews of how actinide species and microorganisms interact have
21 been published (Banaszak, Rittmann, and Reed 1998; Neu, Ruggiero, and Francis 2002).
22 General aspects of this were discussed in Section SOTERM-2.4.1.2. Additionally, the important
23 role of microbial activity through biotic transformations (Francis 1990; Zitomer and Speece
24 1993; Banaszak, Rittmann, and Reed 1998; Rittmann, Banaszak, and Reed 2002; Reed et al.

1 2007) in defining oxidation state distribution of multivalent metals and actinides has been
2 recognized.

3 Although the bioreduction of uranyl and neptunyl species is well established, there are relatively
4 few studies of the bioreduction of plutonyl species. Reed et al. (2007) demonstrate that
5 *Shewanella alga*, a ubiquitous metal-reducing soil bacteria, reduces Pu(V) to Pu(III/IV) species.
6 Icopini, Boukhalfa, and Neu (2007) have shown that *Geobacter* and *Shewanella odeinensis* also
7 reduce higher-valent Pu to Pu(III/IV) species.

8 These Pu data are consistent with the oxidation state predictions in microbially active systems
9 shown in Figure SOTERM-2. It is particularly important to note that Pu(IV) is the expected
10 oxidation state under a wide range of anoxic subsurface conditions, with no Pu(V) or Pu(VI)
11 species expected. The recent Pu bioreduction results confirm that highly reducing conditions are
12 being generated by metal-reducing bacteria under anaerobic growth conditions and support the
13 current WIPP PA assumption that higher-valent actinides cannot persist when the concentration
14 of dissolved actinides is important and microbial activity is prevalent.

15 There are no studies on the bioreduction of Pu(V/VI) under WIPP-relevant conditions.
16 Halophiles (Gillow et al. 2000) typically found and expected to predominate in the WIPP
17 environment have not been studied in the context of their tendency and ability to reduce higher-
18 valent actinides. Since there is a high expectation that geochemical reactions alone will produce
19 an anoxic, strongly reducing environment in the WIPP, halophiles, by analogy, are also expected
20 to cause the bioreduction of multivalent actinides in the WIPP by both indirect cometabolic and
21 direct enzymatic pathways.

22 **SOTERM-3.5.1.3 Thermodynamic Stability of Higher-Valent Plutonium: PuO_{2+x}**

23 It has long been held that Pu oxide, as PuO₂, is the thermodynamically favored form of Pu oxide.
24 This oxide is likely the predominant form of Pu in TRU waste and is believed to be the most
25 important phase under WIPP-related conditions. In the last few years, however, there have been
26 a number of studies that question this key and fundamental assumption.

27 Haschke, Allen, and Morales (2000) report that near-stoichiometric plutonium dioxide reacts
28 with water vapor at temperatures between 25 °C and 350 °C (77 °F and 662 °F) according to the
29 following reaction:

31 Here, water vapor is reduced by polycrystalline PuO₂ to produce hydrogen (H) and a previously
32 unknown higher-oxide PuO_{2+x} with x as large as 0.27. If only Pu(IV) and Pu(V) are present in
33 PuO_{2.27}, this oxide has 46% Pu(IV) and 54% Pu(V). Once formed, the PuO_{2+x} may dissolve in
34 contact with groundwater to form aqueous PuO₂⁺ or PuO₂²⁺ species (Haschke and Ricketts
35 1995).

36 There remains some controversy about the mechanisms that led to the observation of higher-
37 valent Pu in the PuO_{2+x}. This process only occurs under unsaturated conditions at high relative
38 humidities. Haschke, Allen, and Morales (2000) argue that this conversion is due to a chemical

1 reaction (that is, the above reaction has a Gibbs energy less than zero) rather than a radiolysis-
2 induced reaction because the reaction rate is temperature dependent. However, there seems to be
3 some contribution from radiolysis in this process and this may be the dominant mechanism
4 (LaVerne and Tandon 2002). Neither of these mechanisms are expected to impact WIPP
5 repository performance.

6 The behavior of PuO_2 in contact with water was studied as a function of time by means of the
7 short-lived isotope ^{238}Pu , as well as the longer-lived ^{239}Pu (Rai and Ryan 1982b). This study
8 concluded that crystalline PuO_2 , amorphous PuO_2 , and amorphous $\text{PuO}_3 \cdot x\text{H}_2\text{O}$ all convert to a
9 material intermediate between crystalline PuO_2 and a hydrated amorphous material that contains
10 both Pu(IV) and Pu(VI). These authors hypothesized that alpha particles generated by ^{238}Pu or
11 ^{239}Pu irradiated water to generate OH radicals that reacted to form Pu(V) and/or Pu(VI) on the
12 oxide surface. These observations are why the formation of localized oxidizing zones, where
13 some higher-valent Pu can persist, is recognized in the WIPP PA. Reduction of these species,
14 however, leads to a reformation of Pu(IV) hydrous oxide precipitates.

15 The overall issue of a thermodynamic driver for higher-valent Pu oxides, although it has received
16 much recent attention in the literature, is not yet resolved, but has a relatively insignificant
17 impact on the WIPP regardless of the mechanisms at work. A prolonged unsaturated phase in
18 the WIPP could lead to the formation of some PuO_{2+x} , but this will be quickly overwhelmed in
19 an aqueous environment and the higher-valent Pu will be reduced to Pu(III/IV) species, as
20 described in Section SOTERM-3.5.1.1 and Section SOTERM-3.5.1.2. Both DBR and transport-
21 release scenarios assume brine inundation and, correspondingly, the rapid introduction of
22 reducing conditions.

23 **SOTERM-3.5.2 WIPP-Specific Results since the CRA-2004 and the CRA-** 24 **2004 PABC**

25 General studies of Pu in brine have been done by a number of investigators (Büppelmann et al.
26 1986; Büppelmann, Kim, and Lierse 1988; Clark, Hobart, and Neu 1995; Nitsche et al. 1992;
27 Nitsche et al. 1994; Pashalidis et al. 1993; Villareal, Bergquist, and Leonard 2001; Reed et al.
28 1993; Reed, Okajima, and Richmann 1994; Reed and Wygmans 1997). There has also been an
29 assessment of the actinide chemistry in the WIPP CCA (Oversby 2000; Brush, Moore, and Wall
30 2001; U.S. Environmental Protection Agency 2006). These studies confirm reduction of higher-
31 valent Pu under the expected WIPP conditions and establish the key speciation trends for Pu in
32 the WIPP. These trends, however, are captured in the WIPP PA through analogy with Am(III)
33 for Pu(III) and with Th(IV) for Pu(IV).

34 WIPP-specific experiments and progress were made in two important areas since CRA-2004 and
35 CRA-2004 PABC. The first is that a series of experiments to determine the solubility of
36 neodymium (Nd) in the WIPP brine were completed (Borkowski et al. 2008). Nd is an
37 oxidation-state-invariant analog for the III actinides and, in this context, is an analog for the
38 solubility of Pu(III). These results are summarized in Section SOTERM-3.6.2 and support the
39 current WIPP PA solubilities in the CRA-2004 PABC.

40 The second area of progress was in the completion and publication of WIPP-specific
41 experiments that establish the reduction of higher-valent Pu(V/VI) species by reduced iron in the

1 brine. A series of WIPP-specific experiments performed by researchers at Argonne were
 2 confirmed and published (Reed et al. 2006). Additionally, experiments were performed to
 3 further confirm the reduction of higher-valent Pu and establish its reactivity with iron oxides
 4 (Reed et al. 2009).

5 Iron and lead (Pb) have an important role as reducing agents for Pu in the V and VI oxidation
 6 state. Under the conditions expected in the WIPP, iron can exist as Fe(0), Fe(II), and small
 7 amounts of Fe(III) species, and lead can exist as Pb(0) and Pb(II) species. The expected
 8 importance of these two metals is based on the redox-half-reaction potentials for the reduced
 9 metal oxidation states Fe(0/II) and Pb(0/II) relative to Pu(V/VI), and the significant amount of
 10 these two metals present in the WIPP. Whereas, for U, the existence of favorable redox
 11 potentials are somewhat dependent on the speciation of Fe and Pb, the existence of reduced iron
 12 and Pb always lead to favorable redox conditions for the reduction of both Pu(V) and Pu(VI)
 13 species under a wide range of conditions.

14 Two key figures from Reed et al. (2009) that demonstrate the reduction of Pu(V/VI) are shown
 15 (Figure SOTERM-12 and Figure SOTERM-13). In Figure SOTERM-12, both powder and
 16 coupon forms of zero-valent iron led to the rapid (few days) reduction of Pu(V/VI). XANES
 17 analysis confirmed that Pu(IV) was produced.

18
 19 **Figure SOTERM-12. Comparison of the Reactivity of Iron Powder and Iron Coupon**
 20 **Towards Pu(VI). Rapid Reduction/Removal from Solution was**
 21 **Observed at pH 7 (GWB brine) and pH 8 (ERDA-6 brine). This was**
 22 **Somewhat Slower at pH 10 in ERDA-6 Brine (Reed et al. 2009).**

1 In Figure SOTERM-13, the effect of Fe(II) in the iron phases is shown. Overall, the reduction of
 2 Pu(V/VI) is observed over a wide range of conditions in the WIPP brine when either zero-valent
 3 iron, aqueous Fe^{2+} , or Fe(II) phases are present in the WIPP brine. When Fe(III) phases are
 4 present, only sorption, not reduction, is observed. These data provide strong and WIPP-specific
 5 evidence that reduced iron phases will reduce higher-valent Pu to Pu(IV) and support the current
 6 WIPP PA assumptions on oxidation state distribution.

7

11 SOTERM-3.6 Americium and Curium Chemistry

12 There are relatively small quantities of Am in TRU waste (see Table SOTERM-8), but the high
 13 activity of ^{241}Am ($t_{1/2} = 432$ years, 3.443 Ci/g) make Am a key contributor to potential actinide
 14 release from the WIPP. In the WIPP PA, Am is in the trivalent state in all vectors and the
 15 aqueous concentration consists of Am^{3+} complexes and colloidal species.

16 Cm is also present in very small quantities in the WIPP (Table SOTERM-8) and exists primarily
 17 as the ^{244}Cm isotope. The high activity of this isotope ($t_{1/2} = 18.11$ years) makes Cm an important
 18 species in the WIPP at only the very early stages of repository history. It is essentially
 19 unimportant for the PA because it has decayed away by the end of the 100-year period for active
 20 institutional controls. However, other Cm isotopes with longer half-lives are present in the
 21 inventory and are considered by the WIPP PA. The environmental chemistry of Am and Cm are

1 very similar, and most of what is said in this section about the environmental chemistry of Am
2 also applies to Cm.

3 A more detailed review of the literature for Am can be found as part of a recent WIPP report
4 (Borkowski et al. 2008). The solubility of An(III) was measured in the WIPP brine over a wide
5 range of conditions using Nd(III) as a redox-invariant analog. These data support current WIPP
6 PA calculations for the solubility of Pu(III) and Am(III) in the WIPP brine and are also
7 summarized in Borkowski et al. (2008).

8 **SOTERM-3.6.1 Americium and Curium Environmental Chemistry**

9 Am is a 5f electron element and, like other elements of the actinide group, can exist in aqueous
10 solution in several oxidation states. The electrode potentials for some Am couples are presented
11 in Figure SOTERM-14. The trivalent state of Am is the most stable aqueous oxidation state
12

13
14 **Figure SOTERM-14. Redox Potential for Some Am Redox Couples (Silva et al. 1995, p. 74)**

15 (Katz, Seaborg, and Morss 1986, p. 912), and it is quite difficult to oxidize in aqueous solution
16 (Hobart, Samhoun, and Peterson 1982). The trivalent Am ion has an ionic radius of 97.5
17 picometers (pm) (coordination number [CN]=6) and its chemical properties can be used as an
18 analog for Pu(III), which has a similar ionic radius (100 pm at CN=6) and charge density, as well
19 as for Cm(III) (97 pm at CN=6).

20 The *Am(II)* species is italicized to stress that it is only a transient species. As discussed by
21 Marinot and Fuger (1985), there is evidence for the formation of *Am(II)* in aqueous perchlorate
22 solution in the pulse radiolysis experiment. The half-life of this species was estimated to be
23 approximately 5 μ s. This species is not observed during the electroreduction of Am(III) to the
24 metal in noncomplexing media (David, Maslennikov, and Peretrukhin 1990).

25 Cm is also distinguished by the relatively great stability of the III oxidation state with respect to
26 oxidation or reduction (Katz, Seaborg, and Morss 1986, p. 970). The stability of Cm(III) may be
27 attributed to the half-filled f-shell electronic configuration ($5f^7$). The oxidation of Cm(III) is
28 achieved only with the strongest oxidizing agents, and only one report claims evidence for an
29 oxidation state higher than IV (Korpusov, Patrusheva, and Dolidze 1975). The Cm(III) to
30 Cm(IV) transition has not been successfully induced by ozone or electrochemically, and the
31 Cm(IV) phosphotungstate produced by oxidizing with peroxysulfate is considerably less stable
32 than the Am(IV) analog (Katz, Seaborg, and Morss 1986, p. 971). In the reducing environment
33 of the WIPP repository, any higher-valent Cm produced radiolytically would be unstable. For all
34 these reasons, the predominant oxidation state for Cm in the WIPP environment is Cm(III).

1 Higher-valent Am species have also been noted. Am(IV) species, with an ionic radius estimated
 2 by Shannon (1976) to be 85 pm, is only stable in the presence of strongly complexing anions
 3 such as carbonate, fluoride, phosphate, or phosphotungstate, and was never found in any
 4 appreciable amount in trivalent Am solutions.

5 The pentavalent and hexavalent dioxoamericium ions AmO_2^+ and AmO_2^{2+} can be generated
 6 under strongly oxidizing conditions. Free radicals produced from α particles in water readily
 7 reduce these dioxoamericium ions back to Am^{3+} . In concentrated NaCl solution, in which the
 8 radiolysis products are strong oxidants, pentavalent and hexavalent Am are the predominant
 9 species (Büppelmann et al. 1986). Without an oxidant, the pentavalent dioxoamericium ion
 10 slowly disproportionates to AmO_2^{2+} and Am^{3+} . These higher oxidation states are not stable in
 11 natural waters and can be readily reduced by action of reductants naturally present in those
 12 waters.

13 The speciation of Am in groundwater under mildly alkaline conditions is primarily defined by
 14 hydrolysis and carbonate complexation. Hydrolysis is generally represented by the following
 15 reaction:

17 Silva measured the $^{243}\text{Am}(\text{OH})_3(\text{crystalline [cr]})$ and $\text{Nd}(\text{OH})_3(\text{cr})$ solubilities in 0.1 M NaClO_4
 18 solution at 25 ± 1 °C within the pH range 6 to 10 (Silva et al. 1995, p. 79-97). This is the only
 19 study with Am hydroxide using an x-ray-characterized crystalline solid. The solid phase was
 20 prepared by rigorously controlled, high-temperature transformation of $\text{Am}(\text{OH})_3(\text{am})$. Optical
 21 viewing by SEM of the solid samples at the end of the solubility experiments showed no changes
 22 in the crystal. The use of the ^{243}Am isotope diminished α -particle damage of the crystal as a
 23 result of the 17-times-lower specific activity compared to ^{241}Am . The weakness of this
 24 experiment was the relatively short equilibration time of only 48 days. A log (K_{sp}) of 16.6 ± 0.4
 25 was obtained for the $\text{Am}(\text{OH})_3$ phase. The corresponding hydrolysis constants are listed in Table
 26 SOTERM-12. Similar values for Nd(III) hydrolysis were derived from the $\text{Nd}(\text{OH})_3(\text{cr})$
 27 solubility measurements.

28 Stadler and Kim (1988) investigate the pH dependence of $\text{Am}(\text{OH})_3(\text{s})$ solubility in 0.1 M
 29 NaClO_4 and more concentrated Na chloride and perchlorate solutions at 25 ± 0.5 °C. The effect
 30 of α -induced radiolysis on solubility was also studied using different total concentrations of
 31 ^{241}Am . The solid phase was not characterized in this work. Although the solid used in this work
 32 was different than that used by Silva et al. (1995, pp. 275–76), the reported solubility products
 33 are in agreement. It is unclear, however, if the same phase controls the Am solubility in these
 34 two cases, because of markedly different preparation conditions of the starting solids.

35 Kim et al. (1984) measured the solubility of $\text{Am}(\text{OH})_3(\text{s})$ at $I = 0.1$ and 0.3 M NaClO_4 , in the
 36 absence of CO_2 and at $p\text{CO}_2 = 10^{-3.5}$ atm, and attributed the solubility measured in terms of
 37 contributions from the hydroxy, carbonato- and mixed Am hydroxy-carbonato complexes. No
 38 characterization of the solid was reported in this work, so it was assumed to be $\text{AmCO}_3\text{OH}(\text{s})$.
 39 Several investigators found that changes in the solid phase in aqueous suspensions of Am(III)
 40 hydroxide due to aging conditions become evident in hours and continue for weeks. Similar
 41

3
 4 results were reported by Felmy, Rai, and Fulton (1990). These authors measured the solubility of
 5 AmCO₃OH(cr) at pCO₂ = 10⁻³ atm. The change in total Am concentration measured in this work
 6 as a function of pH was similar to that reported by Kim et al. (1984). Similar plots for the
 7 solubility of Nd in 5 M NaCl were measured by Borkowski et al. (2008); however, the Nd
 8 concentrations obtained for the comparable pC_{H+} values were two to three orders of magnitude
 9 greater as a result of the higher ionic strength present.

10 Am complexation by carbonate was extensively investigated by solvent extraction,
 11 spectrophotometry, electromigration, and solubility (Kim et al. 1984; Rösch et al. 1989; Felmy,
 12 Rai, and Fulton 1990; Meinrath and Kim 1991; Nitsche et al. 1995; Torretto et al. 1995). Many
 13 different soluble species have been proposed for the Am-water-carbonate system: pure
 14 carbonate, bicarbonate, and/or mixed hydroxy-carbonate complexes. Silva et al. (1995) carefully
 15 studied and reinterpreted the literature data. It is the consensus in these studies that Am(CO₃)_n⁽³⁻
 16 ²ⁿ⁾, with n = 1, 2 and 3, are the predominant carbonate complexes. According to Silva et al.
 17 (1995), there is no experimental evidence for the existence of a complex with n = 4 even at the
 18 highest carbonate concentrations. The report also suggests that there is no evidence for the
 19 formation of Am(III)-bicarbonate or hydroxy-carbonate complexes in solution. These data are,
 20 however, in disagreement with the more recent work done by Fanghänel and Kim (1998), which
 21 reports spectroscopic evidence for the formation of the n = 4 species.

22 Data reported by Kim et al. (1984) indicate that up to pC_{H+} = ~8.0, the carbonate complexation
 23 does not affect the solubility of Am(III). For the higher pC_{H+}, the presence of carbonate in 0.1-
 24 0.3 M NaClO₄ increases solubility of Am(III) in relation to carbonate-free systems, and at pC_{H+} =
 25 10 this difference is almost 4 orders of magnitude. The predominance of carbonate

1 complexation is observed in the pC_{H^+} range from 7.5 to 10. At higher pC_{H^+} , hydrolysis
2 predominates over carbonate complexation.

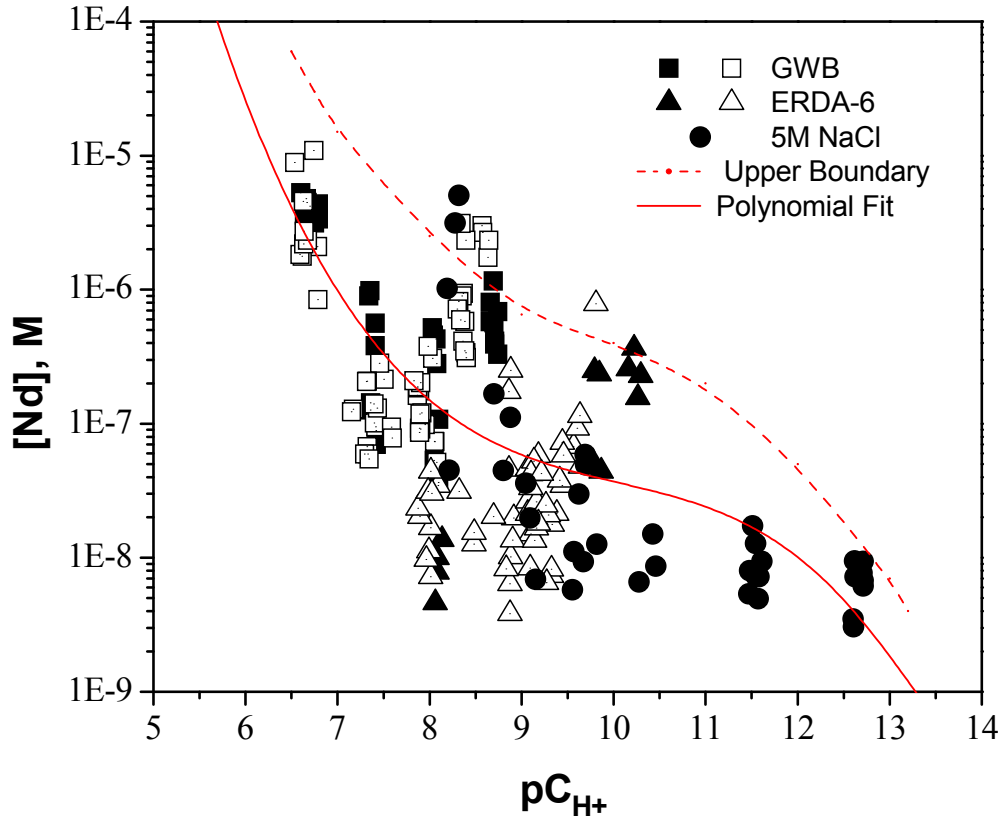

3 **SOTERM-3.6.2 WIPP-Specific Results since the CRA-2004 and the CRA-** 4 **2004 PABC**

5 An extensive series of experiments were performed to determine the solubility of Nd(III) as an
6 analog for Pu(III) and Am(III) solubility in the brine (Borkowski et al. 2008). In this study, the
7 solubility was determined in GWB and ERDA-6 brine, over a pH range of 6-12, and as a
8 function of carbonate concentration. These solubility data extend earlier studies in simplified
9 brines to simulated WIPP brine compositions and cover a broader range of experimental
10 conditions.

11 There are a number of key results and observations from this Nd(III) solubility experimental
12 study. The most important of these are

- 13 1. The solubility data reported for Nd(III) in WIPP-relevant brine systems support current WIPP
14 PA calculations of An(III) solubility, in that the calculated values remain conservative for the
15 reference WIPP conditions. This observation is, however, qualified somewhat by the
16 observations summarized below.
- 17 2. Specific observations and results related to the Nd(III) solubility data include the following:
 - 18 A. Excellent agreement with comparable literature values for Nd(III) solubility in carbonate-
19 free, simplified 5 M NaCl brine study was obtained. This provided an external
20 corroboration of the experimental approach for the only system investigated that can be
21 directly compared to other non-WIPP studies.
 - 22 B. Excellent agreement was obtained between the oversaturation and undersaturation
23 experiments performed. This is a strong indicator that the solubility, rather than steady-
24 state metastable concentrations, was being measured.
 - 25 C. The solubility of Nd(III) in simulated WIPP brine was not strongly influenced by the
26 range of carbonate concentrations considered (as high as a total concentration of 0.01 M).
27 This is largely due to the complexation of Nd^{3+} by borate, already present in the WIPP
28 brine at much higher concentrations, which masks the effects of carbonate.
 - 29 D. The solubility of Nd, in the simplified and simulated brine systems considered, does not
30 exhibit amphoteric behavior. In this context, the solubility of Nd at $pC_{H^+} > 10$ is mostly
31 controlled by hydroxide concentration and decreases with increasing pC_{H^+} . A shoulder to
32 a varying degree, however, is noted in the Nd solubility graphs for $7.5 < pC_{H^+} < 10.5$ as a
33 result of complexation in all three brines investigated.
 - 34 E. The shoulder in the Nd solubility data for ERDA-6 and GWB brine is caused by borate
35 complexation. This establishes borate as the predominant complexant in brine in the
36 pC_{H^+} range of 7.5 to 10 (this includes the current reference pC_{H^+}). The formation
37 constant for this complex was established to be $\log K$ of approximately 3 to 4.

1 It is important to emphasize that the measurement of Nd(III) solubility in GWB and ERDA-6
 2 brines with carbonate showed that there was little effect of carbonate on Nd solubilities in these
 3 brines. This was due to the competition between borate and carbonate in these systems. Borate
 4 is, in fact, the key complexant in the WIPP brine, with its current GWB and ERDA-6
 5 formulations, for An(III). These solubility data, however, support the current calculated III
 6 solubilities in the WIPP PA. It is the competition between borate and carbonate that makes
 7 carbonate a relatively unimportant complexant for the conditions expected in the WIPP. A
 8 composite of all literature values, including our WIPP-specific data, is shown in Figure
 9 SOTERM-15.

10

11 **Figure SOTERM-15. Composite of Nd Solubility Trends Under All Conditions**
 12 **Investigated (Borkowski et al. 2008). Open Symbols Correspond to**
 13 **Undersaturation Experiments and Closed Symbols Correspond to**
 14 **Oversaturation Experiments.**

15 Based on these results, there should be no significant change to the solubility of An(III)
 16 concentrations used in the WIPP PA for the reference case. In effect, although borate
 17 complexation is not currently in the model, the concentrations of III actinides calculated are
 18 conservatively high when compared to the experimental results. The WIPP-relevant data
 19 summarized in this report support current PA calculations performed with the use of the Pitzer
 20 model (U.S. Department of Energy 2004, Appendix PA, Attachment SOTERM) for the values of
 21 3×10^{-7} M and 1.7×10^{-7} M in GWB and ERDA-6, respectively, at pC_{H+}~8.5. The data show

1 that this solubility is at or near the maximum solubility over a wide range of pH, brine
2 composition, and carbonate concentrations.

3 **SOTERM-3.7 Complexation of Actinides by WIPP Organic Chelating Agents**

4 The stability constants for organic ligand-actinide complexation were determined as part of the
5 WIPP ASTP at Florida State University (Choppin et al. 1999). These data are summarized in
6 Table SOTERM-13 and demonstrate some key trends in actinide complexation. For acetate,
7

8 **Table SOTERM-13. Apparent Stability Constants for the Complexation of Organic**
9 **Ligands with Actinides in NaCl Media (Choppin et al. 1999)**

Organic Ligand	Actinide Ion	NaCl (molality)	$\log_{10} \beta_1$
Acetate	Am ³⁺	0.3 to 5	1.44 - 2.2
	Th ⁴⁺	0.3 to 5	3.68 - 4.18
	NpO ₂ ⁺	0.3 to 5	1.05 - 1.8
	UO ₂ ²⁺	0.3 to 4	2.23 - 3.09
Oxalate	Am ³⁺	0.3 to 5	4.17 - 4.63
	Th ⁴⁺	0.3 to 5	7.04 - 7.47
	NpO ₂ ⁺	1.0 to 5.0	3.62 - 4.63
	UO ₂ ²⁺	0.3 to 5	5.82 - 6.7
Citrate	Am ³⁺	0.3 to 5	4.84 - 5.9
	Th ⁴⁺	0.1 to 5	9.31 - 10.18
	NpO ₂ ⁺	0.1 to 5	2.39 - 2.56
	UO ₂ ²⁺	0.3 to 5	7.07 - 7.32
EDTA	Am ³⁺	0.3 to 5	13.76 - 15.1
	Th ⁴⁺	0.3 to 5	15.56 - 16.94
	NpO ₂ ⁺	0.3 to 5	5.45 - 6.7
	UO ₂ ²⁺	0.3 to 4	10.75 - 12.16

10

11 oxalate, and citrate, the strength of the complex formed is in the same order: IV > VI > III > V.
12 For EDTA, the VI and III are switched. For the most part, the III and IV actinides, which are the
13 two most important oxidation states in the WIPP, are strongly affected by organic complexation
14 and thus can out-compete carbonate and hydrolysis if the organic concentrations are high
15 enough. Of the four organic chelating agents considered, only citrate and EDTA are expected to
16 form strong enough complexes to influence the speciation of actinides and potentially increase
17 actinide concentrations under the expected conditions in the WIPP.

18 **SOTERM-3.8 Actinide Colloids**

19 Actinide colloids in the WIPP are potentially important since the actinide source term is defined
20 by the WIPP PA as the sum of contributions from dissolved actinide species and mobile colloidal
21 actinide species (see U.S. Department of Energy 2004, SOTERM 2004) for a more detailed

1 discussion of WIPP-relevant colloids). The importance of colloids in the migration and transport
2 of actinide contaminants, although it continues to receive attention in the literature, remains
3 somewhat controversial and difficult to prove. In this context, the consideration of colloidal
4 enhancement of actinide concentrations by the WIPP PA is, at least in part, a conservatism that is
5 built into the overall PA approach. In this context, the sorption of colloidal actinides onto fixed
6 substrates and their filtration in low-porosity media will also reduce the mobile colloidal actinide
7 source term, but no credit is currently being taken for this potentially significant reduction in
8 colloidal concentrations.

9 Actinide colloids or pseudocolloids may be generated in the WIPP repository as a result of

- 10 1. Hydrolysis (intrinsic chemistry).
- 11 2. The interactions of dissolved actinide species with microbially derived colloids or colloids
12 formed due to the corrosion of steel and waste constituents.
- 13 3. The hydrodynamic entrainment of colloidal-sized mineral fragments, as well as several other
14 mechanisms. The formation of colloids could enhance actinide release in two ways. First,
15 increased actinide concentration will increase the magnitude of DBR release and the effective
16 actinide source term concentration for transport through the Culebra. Second, colloids have
17 very different transport properties than dissolved species, and are predicted to migrate more
18 rapidly in the subsurface. This transport mechanism could enhance the overall actinide
19 release in the WIPP through migration pathways in the Culebra member and the Salado.

20 In this section, the general environmental aspects of colloid-enhanced transport in the subsurface
21 are discussed, along with an update of relevant WIPP-specific results since the CRA-2004
22 PABC.

23 **SOTERM-3.8.1 Actinide Colloids in the Environment**

24 The potential for colloidally-enhanced transport of actinides in the subsurface continues to
25 receive much attention in the literature. A key role of colloids in actinide transport has been
26 proposed to explain actinide migration at Rocky Flats (LoPresti, Conradson, and Clark 2007), the
27 Nevada Test Site (Kersting et al. 1999; Zavarin et al. 2003), Hanford (Dai, Buesseler, and Pike
28 2005), the Savannah River Site (Dai, Kelly, and Buesseler 2002), and the Mayak site (Novikov
29 et al. 2006). Colloidal transport at these sites provides an explanation for subsurface actinide
30 migration that exceeds the rates predicted for dissolved actinide species. There continues to be
31 very weak evidence for significant transport of colloids, once formed, in natural systems.

32 An important theme to recent field observations of actinide colloids is the tendency of Pu, as
33 Pu(IV), to form iron and manganese (Mn) oxide pseudocolloids. The colloidal transport of Pu in
34 the far-field was investigated by Novikov et al. (2006) at the Mayak site in Russia. They found
35 that the mobility of Pu in groundwater was facilitated by submicron-sized colloids. Pu(IV)
36 hydroxides or carbonates adsorbed on amorphous iron oxide colloids were most transported.
37 These Pu colloids were essentially removed from groundwater, leading to a drop in the Pu
38 concentration from 1000 becquerel (Bq)/L to 0.16 Bq/L over a distance of 3 km.

1 The field observations are supported by laboratory studies that show a high tendency of lower-
 2 valent actinides to form iron and Mn pseudocolloids in environmentally relevant systems.
 3 Zavarin et al. (2003) shows that, at pH 8, there is a strong sorption of Pu(IV) in groundwater to
 4 birnessite (Mn-oxide) and goethite (Fe-oxide) rather than clinoptilolite (a zeolite) and calcite.
 5 Sorption was rapid and equilibrium was reached after 24 hours. Complexation with carbonate
 6 reduced Pu(IV) sorption to clinoptilolite about 15%. For iron and Mn oxides, Pu(V) sorption
 7 was also rapid, but led to the reduction of Pu(V) to Pu(IV). Khasanova et al. (Khasanova et al.
 8 2007) also studied iron and Mn oxide interactions with actinides and saw a strong association
 9 between the dissolved actinide species and the oxides.

10 The potential formation of actinide pseudocolloids by association of dissolved actinides with
 11 biogenic and humic (natural) organics has also been established in the laboratory and the field.
 12 Santschi et al. (Santschi, Roberts, and Guo 2002), Asbury et al. (Asbury et al. 2001), and
 13 Orlandini, Penrose, and Nelson (1986) all show that actinides associate strongly with natural
 14 organics. These have been implicated as a potential explanation for actinide migration at Rocky
 15 Flats and in near-surface groundwater transport as a result of fallout.

16 Lastly, the formation of intrinsic colloids (colloids that are polymers of actinides) are important
 17 because they potentially add to the concentration of actinides in groundwater, but also because
 18 they potentially contribute to measured solubilities if care is not taken to properly account for
 19 their formation. The tendency of actinides to hydrolyze and to polymerize to form intrinsic
 20 colloids follows the order (Cleveland 1979, pp. 11–46; Choppin 1983; Kim 1991; Lieser et al.
 21 1991)

23 The most well known and well studied actinide intrinsic colloid is the Pu(IV) intrinsic colloid,
 24 which has been used as a basis of comparison for investigating intrinsic colloids of other
 25 actinides. A discussion of colloidal Th, also in the IV oxidation state, was presented in Section
 26 SOTERM-3.2.

27 The most convincing and consistent explanation for the chemistry of these Pu(IV) intrinsic
 28 colloid is presented by Johnson and Toth (1978). Pu polymerization occurs nearly immediately
 29 after the first hydrolysis occurs. The following reaction involving polymerization of two
 30 hydrolyzed species by loss of H₂O (olation) is proposed:

33 Aging or maturation of the polymer then occurs by loss of H₂O (olation) as follows:

36 An important insight into the important role of Pu polymer formation was reported by Neck et al.
 37 (2003), which investigated the solubility of Pu hydroxides/hydrous oxides under reducing
 38 conditions and in the presence of oxygen. The experimental data and thermodynamic
 39 calculations show that, under reducing conditions in the stability field of water, Pu(OH)₃(s) is not

1 stable and it converts to $\text{PuO}_2(\text{s,hyd})$. It also found that small Pu(IV) colloids/polymers, present
2 in neutral to alkaline solutions at the constant level of $\log[\text{Pu(IV)}]_{\text{coll}} = -8.3 \pm 1.0$, play an
3 important role in defining the redox potentials in these systems. The experimental results in
4 these systems including colloid species can be described in terms of equilibrium
5 thermodynamics. These data argue for a thermodynamically stable Pu(IV) oxidation state in the
6 WIPP.

7 Lastly, there is a growing debate about the care needed in solubility studies to account for
8 colloids in the solubilities measured—which is not a trivial problem, as the colloids are often
9 very small (< 20 nm) and difficult to detect experimentally. The role of colloid formation,
10 especially for An(IV) solubilities, was discussed by Fanghänel and Neck, who state, “The
11 formation of amorphous and crystalline solids and the discrepancies between the corresponding
12 experimental solubility data may be explained as an effort of particle size. ... the predicted
13 solubilities are often significantly lower than experimental data indicating that that solubility is
14 controlled by the surface properties” (Fanghänel and Neck 2002). In this context, existing
15 solubility data in the literature may include significant colloidal enhancement and overestimate
16 the corresponding solubility.

17 In conclusion, there is ample evidence that colloids can form and are readily generated in the
18 laboratory. Intrinsic colloids tend to be very low in concentration and comparable to the
19 solubilities observed. Significant enhancement can be observed when actinides associate with
20 oxide mineral colloids and natural and biogenic organic species. However, there remains high
21 uncertainty in the ability of these colloidal species to migrate in the subsurface. This key issue
22 was raised by Kersting et al. (1999) for the Nevada Test site, Dai et al. for the Hanford and
23 Savannah River site (Dai, Kelly, and Buessler 2002; Dai, Buessler, and Pike 2005), and strong
24 attenuation was noted at the Mayak site (Novikov et al. 2006). In the WIPP, with its very low
25 porosity, it is reasonable to predict that the transport of colloids is likely to be negligible; the
26 only significant concern would be the colloidal contribution to dissolved concentrations for
27 DBR-type release.

28 **SOTERM-3.8.2 WIPP-Specific Results since the CRA-2004 PABC**

29 There are no new experiments since the CRA-2004 PABC that investigate the formation and
30 transport of actinide colloids under WIPP-relevant conditions. Recently published results (Wall
31 and Mathews 2005) demonstrate that the presence of MgO in the WIPP brine will significantly
32 reduce the concentration of humic acids (HA); this occurs after a relatively short period of time
33 (12 to 60 days) when a negligible concentration of HA was observed in the system. This
34 important observation was attributed to MgO-facilitated HA precipitation and/or sorption of the
35 HA onto the MgO surface. Treatment of colloids in the PA are the same as in CRA-2004 and
36 CRA-2004 PABC.

37 **SOTERM-3.9 Changes in Actinide Speciation Information since the CRA-** 38 **2004 and the CRA-2004 PABC**

39 There are no significant changes in the general approach and assumptions used to understand and
40 predict actinide behavior in the WIPP from a PA perspective. Specifically,

- 1 • Oxidation state distributions for the TRU actinides, and correspondingly, assumptions
2 regarding their solubility calculations using redox-invariant analogs, have not changed.
- 3 • Predicted and calculated solubilities for Pu and Am oxidation states, which are the key
4 actinides from the perspective of PA, have not changed.
- 5 • Inventory assumptions regarding the amounts of organic chelating agents and actinides in
6 TRU waste are being updated annually.
- 7 • The recognition that microbial colloids are the most likely to be generated in the WIPP has
8 not changed. Treatment of colloids in PA are the same as in CRA-2004 and CRA-2004-
9 PABC.

10 There are new data, within and outside the WIPP project, that continue to support and/or expand
11 the robustness of the current PA assumptions. The most important of these are

- 12 • Extensive data from the Karlsruhe (German) program for III and IV actinides in simplified
13 brine systems. These data support existing PA assumptions and show that they extend
14 beyond the relatively narrow pH range considered in the WIPP PA. This is especially
15 important for higher-pH environments, where it was previously thought that solubilities
16 increase greatly.
- 17 • WIPP-specific results are reported in three key areas:
 - 18 – An(III) solubility in simulated WIPP brines over a wide range of conditions using Nd(III)
19 as an analog for Pu(III) and Am(III). These data support current PA solubilities for the
20 III actinides, but show that complexation with borate explains the observed trends with
21 pH and little or no effect of carbonate.
 - 22 – The reduction of Pu(V/VI) in WIPP brine by reaction with reduced iron species. These
23 results provide additional support to past observations that higher-valent actinides cannot
24 persist in the WIPP in the presence of reduced iron. This strongly supports current PA
25 assumptions on oxidation state distribution for both Am and Pu.
 - 26 – The solubility of U(VI) in simulated WIPP brine over a wide range of conditions in the
27 absence of carbonate. These data support the current WIPP PA assumptions about the
28 solubility of U(VI).

29 Lastly, there are some new developments reported in the literature that, although not directly
30 relevant to the WIPP, indirectly affect how the actinide chemistry in the WIPP is viewed. The
31 most important of these are

- 32 • The potential role of Ca^{2+} and Mg^{2+} to form soluble species in the presence of carbonate at
33 high pH. This has been evaluated in the WIPP case and is not likely to affect actinide
34 solubility in the range of conditions expected in the WIPP.
- 35 • Growing recognition that microbes, under most anaerobic conditions, reduce higher-valent
36 actinides in the subsurface.

- 1 • Additional results on the potential effects of radiolysis on brine systems. It is clear that
- 2 mechanisms exist that can lead to the oxidation of actinides when no reducing agents are
- 3 present in the brine. This could create localized oxidation in the WIPP, but WIPP-specific
- 4 experiments show this to be easily overwhelmed by the expected microbial and reduced-iron
- 5 effect on actinide redox.

1 **SOTERM-4.0 Calculation of the WIPP Actinide Source Term**

2 The calculation of the WIPP actinide source term was performed for the CRA-2004 PABC
 3 (Brush and Xiong 2005a) using the computer code FMT. This is the baseline PA currently being
 4 used for CRA-2009. A general description of the modeling approach to establish the actinide
 5 source term for the WIPP PA is described in this section. The approach used in the CRA-2004
 6 PABC calculations and the results obtained were published in a series of reports and documents.
 7 These are listed below with supporting letters and documentation.

8 **Table SOTERM-14. List of Documents and Reports that Support the CRA-2004 PABC**

1 **SOTERM-4.1 Overview of WIPP Approach to Calculate Actinide Solubilities**

2 The overall approach used to establish the actinides important in WIPP releases and calculate
3 their solubilities for use in the WIPP PA is summarized in this section. This approach consists of
4 the following:

- 5 • Assessing the WIPP inventory and regulations that govern the application of the WIPP
6 certification to determine the likely actinides of interest and, correspondingly, the key waste
7 components that may affect their solubility.
- 8 • Establishing a conceptual model for the key subsurface interactions and release mechanisms
9 and using a combination of literature review and WIPP-specific experimental results to
10 establish the likely oxidation state distribution, the species that affect actinide solubility, and
11 the parameters required to model the system at high ionic strength. This approach featured
12 the following:
 - 13 – Conservative assumptions, within the bounds of the conditions expected, for the
14 oxidation state distribution.
 - 15 – Use of redox-invariant analogs for multivalent actinides to determine formation constants
16 and establish oxidation-specific solubilities.
 - 17 – Use of the Pitzer formalism and associated parameters to model solubilities at the high
18 ionic strengths present. The Pitzer approach is recognized as the best approach for $I > 0.3$
19 M in brine systems.
- 20 • Calculating the solubility of the key actinides in the WIPP using the FMT code. The
21 solubilities are modeled in reacted GWB and ERDA-6 brines, which are expected to bracket
22 the range in the composition of the brine expected. This code assigns the actinides to the key
23 species by minimizing the total free energy of the system while satisfying charge-balance and
24 mass-balance constraints based on the standard chemical potentials assigned to each species.
- 25 • Establishing the effects of colloids and organic complexation, separately and simultaneously,
26 on the solubilities calculated.
- 27 • Tabulating and assigning uncertainty distributions in the range of expected conditions and
28 brine compositions to these solubility data.

29 This range of possible solubilities for a wide range of possible conditions defines the actinide
30 source term provided to the WIPP PA for the calculation of TRU release from the WIPP.

31 **SOTERM-4.2 Use of Oxidation-State-Invariant Analogs**

32 The solubility and speciation of multivalent actinides are often investigated with lanthanide and
33 actinide analogs that mimic the property of interest but, for varying reasons, provide an
34 advantage to the experimenter. The best example of this, used extensively in the WIPP modeling
35 approach, is the use of redox-invariant analogs for the multivalent actinides, most notably Pu, to

1 determine oxidation-state-specific properties (e.g., solubility or complexation). The advantage of
2 these types of analogs is that they remove the uncertainty of oxidation-state change from the
3 experiment, which is a complexity that can often lead to uncertain or incorrect interpretations of
4 the results obtained.

5 For the TRU actinides, the redox-invariant analogs used are lanthanides or other actinides.
6 Lanthanides, as 4f-electron elements, possess physical and chemical characteristics that make
7 them good analogs for the actinides when they are redox-invariant under the conditions of the
8 experiment. Correspondingly, actinides with their 5f-electron character also have good physical
9 and chemical properties to be analogs for other actinides if they also have redox stability under
10 WIPP-relevant conditions. This analog approach, although sometimes criticized in the literature,
11 considerably simplifies experimental design and consequently improves the reliability of the
12 experimental data (Choppin 1999).

13 A key argument for the use of analogs in WIPP-related experiments is that key complexants that
14 define actinide solubility in the WIPP are hard-donor complexants (e.g., hydroxide, carbonate,
15 borate, chloride, and/or sulfate). The use of lanthanides as analogs for actinides is based on
16 observations in many extraction systems, along with the associated crystallographic data
17 (Siekierski 1988) that show they are good analogs for compounds containing hard donor ligands
18 (oxygen) where the cation-anion interactions are primarily electrostatic in nature. In this context,
19 Nd(III) is a good analog for the chemical behavior of Am(III) and Pu(III) under most
20 circumstances in the WIPP. Not only do these species have the same 3+ charge, they also have
21 similar ionic radii for coordination number 6 (CN=6): 97.5 pm for Am³⁺, 98.3 pm for Nd³⁺, and
22 100 pm for Pu³⁺ (Shannon 1976). In this context, the magnitudes of electrostatic attractions
23 between these metal ions and corresponding ligands will be similar, yielding comparable
24 thermodynamic stabilities.

25 Th is used by the WIPP as a redox-invariant analog for Pu(IV), U(IV), and Np(IV). The use of
26 the Th⁴⁺ stability constants to represent the other An(IV) species is conservative. Th⁴⁺ is the
27 largest of the tetravalent actinide ions. It therefore has the lowest charge density and,
28 correspondingly, relatively weaker ionic interactions when compared to the other tetravalent
29 actinides. This is best exhibited by its lower tendency towards hydrolysis and intrinsic polymer
30 formation relative to the other actinides (see Section SOTERM-3.2). For these reasons, the use
31 of Th⁴⁺ as an analog is conservative, as Th will likely be the most soluble of the actinides in the
32 tetravalent state under comparable WIPP-relevant conditions.

33 To a lesser extent, actinides are analogs for each other, depending on the oxidation state. Np(V),
34 which has much greater redox stability than Pu(V) and much more favorable spectroscopy, is
35 often used as an analog for Pu(V). U(VI), which is much more redox stable than Pu(VI) and
36 Np(VI), is also used as an analog for these TRU actinides, although this breaks down somewhat
37 quickly. Am(III) and Cm(III) are also excellent analogs for Pu(III) as a result of their much
38 greater redox stability and comparable ionic radii.

1 **SOTERM-4.3 Actinide Inventory and Oxidation State Distribution in the**
 2 **WIPP**

3 The actinide inventory used in CRA-2004 PABC is given in Table SOTERM-15 (Leigh, Trone
 4 and Fox 2005). This is based on the inventory given in Table SOTERM-7 projected to the year
 5 2033, which is the projected year for the closure of the WIPP.

6 **Table SOTERM-15. WIPP Radionuclide Inventory at Closure (in 2033) Used in PABC-**
 7 **2005 Calculations (Leigh, Trone, and Fox 2005)**

Radionuclide	Activity (Ci)	Amount (kg)	Element-Specific Inventory
²²⁹ Th	5.21E+00	2.64E-02	8.81 Ci 3.11E+04 kg
²³⁰ Th	1.80E-01	8.73E-03	
²³² Th	3.42E+00	3.11E+04	
²³³ U	1.23E+03	1.27E+02	1.80E+03 Ci 6.47E+05 kg
²³⁴ U	3.44E+02	5.52E+01	
²³⁵ U	5.01E+00	2.32E+03	
²³⁶ U	2.87E+00	4.43E+01

⁹⁰ Sr (see Note ^a)	1.76E+05	1.29E+00	1.76E+05 Ci (1.29 kg)

^a Fission products are not TRU, but are considered in the PA to calculate overall release

8
 9 The oxidation states used by the WIPP PA to model actinide solubility are tabulated in Table
 10 SOTERM-16. Also included are the assumed abundance percent of each oxidation state and the
 11 speciation data set used in FMT for each oxidation state. This table is based on a general
 12 understanding of the corresponding actinide chemistry summarized in Section SOTERM-3.0.

13 A number of conservative assumptions are reflected in this table. The most important
 14 assumptions are

1 **Table SOTERM-16. Oxidation States of the Actinides in the WIPP as Used in the CRA-**
 2 **2004 PABC**

Actinide Element	Oxidation States, Abundance (%), and Analog Used (If Any)				
	Oxidation State ^{a,b}				FMT Speciation Data Used
	III	IV	V	VI	
Thorium	—	100 %	—	—	Thorium
Uranium	—	50 %	—	50 %	1 mM assumed for VI, Th for IV
Neptunium	—	50%	50 %	—	Np for V Th for IV
Plutonium	50 %	50 %	—	—	Am for III Th for IV
Americium	100 %	—	—	—	Americium
Curium	100 %	—	—	—	Americium

^a Oxidation state distributions (percentages) refer to the percent of PA vectors that have 100% of the specified oxidation state.

^b In PA calculations the distribution of oxidation states is correlated for U, Np, and Pu such that the states for all three elements are simultaneously either in the lower oxidation state (U(IV), Np(IV), and Pu(III)) or in the higher oxidation state (U(VI), Np(V), and Pu(IV)).

- 3
- 4 1. Use of 1 mM concentration for the solubility of U(VI). The actual solubility of U(VI) in the
 5 WIPP under the expected range of conditions is estimated to be <0.1 mM.
- 6 2. Use of Th as an analog for the IV actinides (see Section SOTERM-4.1 and Section
 7 SOTERM-3.2).
- 8 3. The assumption that 50% of the vectors have Pu(III) and 50% of the vectors have Pu(IV).
 9 The predominant Pu species expected is Pu(IV), although some Pu(III) is possible as a
 10 transient (see discussions in Section SOTERM-3.3). This is conservative because Pu(III) is
 11 approximately 6 to 10 times more soluble than corresponding Pu(IV) phases.
- 12 4. The assumption is that 50% of the vectors have U(IV) and 50% of the vectors have U(VI).
 13 The predominant uranium species expected is U(IV), which is approximately four 4 orders of
 14 magnitude less soluble than U(VI), based on current assumptions.

15 **SOTERM-4.4 Actinide Speciation Reactions Used in the FMT Model**

16 The version of the FMT code used in the CRA-2004 PABC was FMT_050405.CHEMDAT
 17 (Xiong 2005). The data in FMT was previously described in a series of memoranda by
 18 Giambavlo (Giambavlo 2002a, 2002b, 2002c, 2002d, 2002e, 2003). The most recent database
 19 iteration included some minor changes from previous versions that go beyond those described in
 20 these memoranda:

- 21 • The chemical potential for the solubility of Th(OH)₄ (s) was changed.
- 22 • The effects of hydromagnesite and calcite precipitation were added.

1 SOTERM-4.4.1 The III Actinides: Pu(III), Am(III), Cm(III)

2 The thermodynamic database for the III actinides currently used in FMT was described by
 3 Giambalvo (2002a). Nd, Am, and Cm are generally used to establish solubility of An(III)
 4 because, unlike plutonium, they have redox-stable trivalent oxidation states. Speciation and
 5 solubility data for the III actinides were parameterized for use in the Pitzer activity-coefficient
 6 model by Felmy et al. (1989) for the Na^+ - Pu^{3+} - Cl^- - H_2O system; by Felmy, Rai, and Fulton
 7 (1990) for the Na^+ - Am^{3+} - OH^- - HCO_3^- - H_2O system; by Rai, Felmy, and Fulton (1995) for the Na^+ -
 8 Am^{3+} - PO_4^{3-} - SO_4^{2-} - H_2O system; and by Rao et al. (1996) for the Na^+ - Nd^{3+} - CO_3^{2-} - HCO_3^- - H_2O
 9 system. For this reason, FMT uses the Am(III) data to calculate the solubility for all the III
 10 actinides. A diagram of the predominant species for Am is shown in Figure SOTERM-16.

11 The inorganic aqueous and solubility-limiting species featured in the model for Am(III) are

Am(III) Reactions	log K	
$\text{Am}^{3+} + \text{CO}_3^{2-} \rightleftharpoons \text{AmCO}_3^+$	8.1	(SOTERM.34)
$\text{Am}^{3+} + 2\text{CO}_3^{2-} \rightleftharpoons \text{Am}(\text{CO}_3)_2^-$	13.0	(SOTERM.35)
$\text{Am}^{3+} + 3\text{CO}_3^{2-} \rightleftharpoons \text{Am}(\text{CO}_3)_3^{3-}$	15.2	(SOTERM.36)
$\text{Am}^{3+} + 4\text{CO}_3^{2-} \rightleftharpoons \text{Am}(\text{CO}_3)_4^{5-}$	13.0	(SOTERM.37)
$\text{Am}^{3+} + \text{OH}^- \rightleftharpoons \text{AmOH}^{2+}$	6.4	(SOTERM.38)
$\text{Am}^{3+} + 2\text{OH}^- \rightleftharpoons \text{Am}(\text{OH})_2^+$	12.3	(SOTERM.39)
$\text{Am}^{3+} + 3\text{OH}^- \rightleftharpoons \text{Am}(\text{OH})_3(\text{aq})$	16.3	(SOTERM.40)
$\text{Am}^{3+} + \text{Cl}^- \rightleftharpoons \text{AmCl}^{2+}$	0.24	(SOTERM.41)
$\text{Am}^{3+} + 2\text{Cl}^- \rightleftharpoons \text{AmCl}_2^+$	-0.74	(SOTERM.42)
$\text{Am}^{3+} + \text{SO}_4^{2-} \rightleftharpoons \text{Am}(\text{SO}_4)^+$	3.25	(SOTERM.43)
$\text{Am}^{3+} + 2\text{SO}_4^{2-} \rightleftharpoons \text{Am}(\text{SO}_4)_2^-$	3.7	(SOTERM.44)
$\text{Am}^{3+} + \text{OH}^- + \text{CO}_3^{2-} \rightleftharpoons \text{AmOHCO}_3(\text{s})$	22.7	(SOTERM.45)
$\text{Na}^+ + \text{Am}^{3+} + 2\text{CO}_3^{2-} + 6\text{H}_2\text{O} \rightleftharpoons \text{NaAm}(\text{CO}_3)_2 \cdot 6\text{H}_2\text{O}(\text{s})$	21.4	(SOTERM.46)
$\text{Am}^{3+} + \text{PO}_4^{3-} \rightleftharpoons \text{AmPO}_4(\text{cr})$	24.8	(SOTERM.47)

12
 13 In these reactions, “aq,” “cr,” and “s” are the abbreviations for aqueous, crystalline, and solid,
 14 respectively. The An(III) database was extended to mixed Na^+ - CO_3^{2-} - Cl^- media, and was shown
 15 to reproduce the independently measured solubility of $\text{NaAm}(\text{CO}_3)_2(\text{s})$ in 5.6 M NaCl (Runde
 16 and Kim 1994) and the measured Nd(III) solubility in the WIPP brine (Borkowski et al. 2008).

17 SOTERM-4.4.2 The IV Actinides: Th(IV), U(IV), Pu(IV), Np(IV)

18 The IV actinides addressed by the WIPP PA are Th(IV), U(IV), Pu(IV), and Np(IV). The
 19 variation in charge-to-radius ratio for the tetravalent actinides is greater than for actinides in
 20 other oxidation states (Cotton and Wilkinson 1988, pp. 11–46), and larger differences in the
 21 chemical behavior among the IV actinides is expected. The application of the Th(IV) model to
 22 the other IV species is more uncertain, yet still conservative because Th(IV) is the most soluble
 23 of these elements under WIPP conditions. The model was evaluated against data for Pu(IV) and
 24 Np(IV) solubility and demonstrated to predict the chemical behavior of these actinides
 25 conservatively.

1
 2 **Figure SOTERM-16. Predominant Am Species as a Function of pH and E_h Based on the**
 3 **Speciation Reactions (SOTERM.34) to (SOTERM.47) (Richmann**
 4 **2008)**

5 The thermodynamic database for the IV actinides currently used in FMT was described by
 6 Giambalvo (2002c). Speciation and solubility data for Th(IV) were parameterized for the Pitzer
 7 activity-coefficient model for the Na^+ - K^+ - Mg^{2+} - Cl^- - SO_4^{2-} - CO_3^{2-} - HCO_3^- - OH^- - H_2O system. This
 8 model requires the species Th^{4+} , $\text{Th}(\text{OH})_2\text{SO}_4$ (s), $\text{Th}(\text{SO}_4)_3^{2-}$, $\text{Th}(\text{SO}_4)_2$ (aq), ThO_2 ,
 9 $\text{Th}(\text{OH})_4$ (aq), $\text{Th}(\text{OH})_3\text{CO}_3^-$, and $\text{Th}(\text{CO}_3)_5^{6-}$ to describe the data pertinent to the WIPP (Felmy,
 10 Mason, and Rai 1991; Rabindra et al. 1992; Felmy et al. 1996). A diagram of the predominant
 11 Th speciation, based on Reactions (SOTERM.48) to (SOTERM.59), is shown in Figure
 12 SOTERM-17.

5 The inorganic aqueous and solubility-limiting species featured in the IV model are:

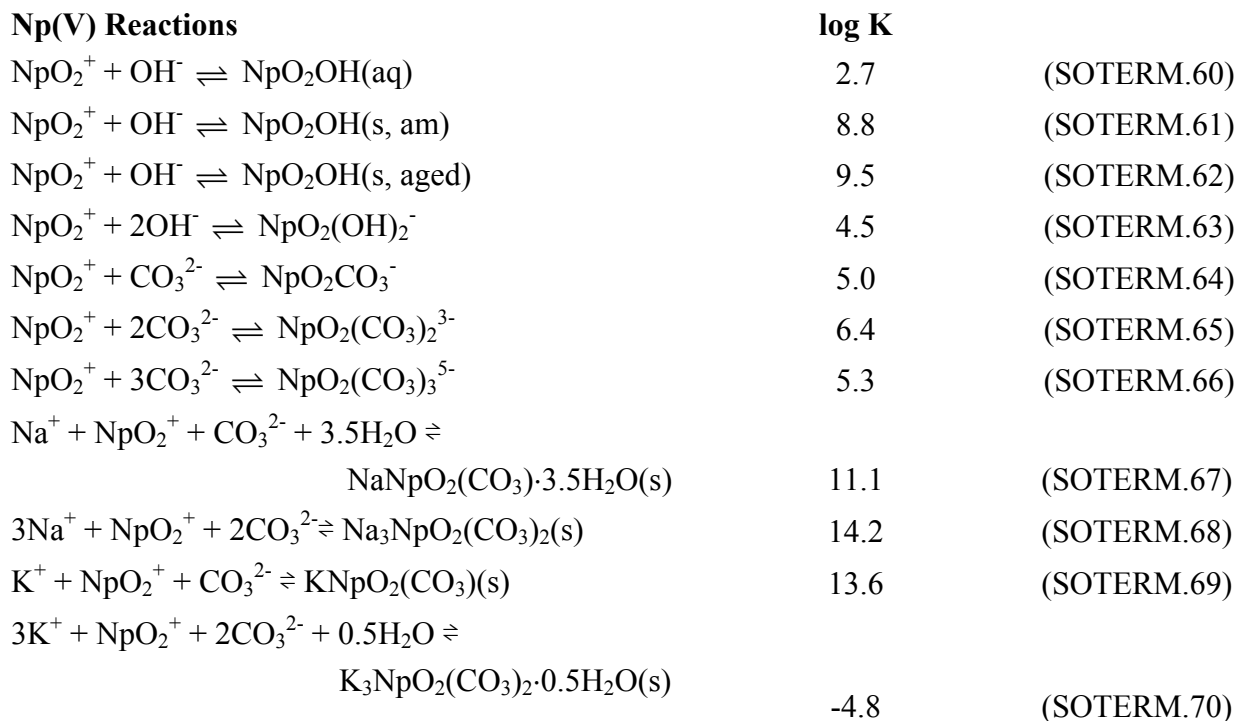

Th(IV) Reactions	log K	
$\text{ThO}_2(\text{am}) + 2\text{H}_2\text{O} \rightleftharpoons \text{Th}(\text{OH})_4(\text{aq})$	-7.0	(SOTERM.48)
$\text{Th}^{4+} + 4\text{OH}^- \rightleftharpoons \text{Th}(\text{OH})_4(\text{aq})$	38.5	(SOTERM.49)
$\text{Th}^{4+} + 3\text{OH}^- + \text{CO}_3^{2-} \rightleftharpoons \text{Th}(\text{OH})_3\text{CO}_3^-$	38.3	(SOTERM.50)
$\text{Th}^{4+} + 5\text{CO}_3^{2-} \rightleftharpoons \text{Th}(\text{CO}_3)_5^{6-}$	27.1	(SOTERM.51)
$\text{Th}^{4+} + 2\text{SO}_4^{2-} \rightleftharpoons \text{Th}(\text{SO}_4)_2(\text{aq});$	11.6	(SOTERM.52)
$\text{Th}^{4+} + 3\text{SO}_4^{2-} \rightleftharpoons \text{Th}(\text{SO}_4)_3^{2-};$	12.4	(SOTERM.53)
$\text{Th}^{4+} + 2\text{SO}_4^{2-} + 9\text{H}_2\text{O} \rightleftharpoons \text{Th}(\text{SO}_4)_2 \cdot 9\text{H}_2\text{O}(\text{s});$	13.0	(SOTERM.54)
$\text{Th}^{4+} + 2\text{SO}_4^{2-} + 8\text{H}_2\text{O} \rightleftharpoons \text{Th}(\text{SO}_4)_2 \cdot 8\text{H}_2\text{O}(\text{s})$	12.9	(SOTERM.55)
$\text{Th}^{4+} + 2\text{Na}^+ + 3\text{SO}_4^{2-} + 6\text{H}_2\text{O} \rightleftharpoons$ $\text{Th}(\text{SO}_4)_2 \cdot \text{Na}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}(\text{s})$	17.6	(SOTERM.56)

1
2 **SOTERM-4.4.3 The V Actinides: Np(V)**
3 The only V actinide of interest to the WIPP is Np(V), which exists as the neptunyl ion, NpO_2^+ .
4 Pu(V), which can be formed under some conditions, is transitory and not expected to persist in
5 significant quantities in the WIPP. The base model for Np(V) comes from Fanghänel, Neck, and
6 Kim (1995), constructed for the German repository program.

7 The thermodynamic database for the V actinides currently used in FMT is described by
8 Giambalvo (2002d). Np(V) speciation and solubility were parameterized in the Pitzer activity-
9 coefficient model for the Na^+ - K^+ - Mg^{2+} - Cl^- - SO_4^{2-} - CO_3^{2-} - HCO_3^- - OH^- - H_2O system. The model
10 requires the aqueous species NpO_2^+ , $\text{NpO}_2\text{OH}(\text{aq})$, $\text{NpO}_2(\text{OH})_2^-$, $\text{NpO}_2\text{CO}_3^-$, $\text{NpO}_2(\text{CO}_3)_2^{3-}$, and
11 $\text{NpO}_2(\text{CO}_3)_3^{5-}$, and the solid species $\text{NpO}_2\text{OH}(\text{am})$, $\text{NpO}_2\text{OH}(\text{aged})$, $\text{Na}_3\text{NpO}_2(\text{CO}_3)_2(\text{s})$,
12 $\text{KNpO}_2\text{CO}_3 \cdot 2\text{H}_2\text{O}(\text{s})$, $\text{K}_3\text{NpO}_2(\text{CO}_3)_2 \cdot 0.5\text{H}_2\text{O}(\text{s})$, and $\text{NaNpO}_2\text{CO}_3 \cdot 3.5\text{H}_2\text{O}(\text{s})$ to explain the
13 available data. The predominant species for Np(V) are shown in Figure SOTERM-18.

14 The inorganic aqueous and solubility-limiting species used are:

15

1
2 **Figure SOTERM-18. Predominant Species Diagram for Np as a Function of pH and Eh**
3 **Based on the Np Speciation Data Reactions (SOTERM.60) to**
4 **((SOTERM.70) (Richmann 2008)**

5 **SOTERM-4.4.4 The VI Actinides: U(VI)**

6 The An(VI) FMT model has not been developed sufficiently for reliable use in predicting
7 concentrations of this oxidation state in the WIPP brines under various solution conditions.
8 Although uranyl carbonate can be successfully modeled, the hydrolysis behavior of U(VI) is
9 quite complicated and no satisfactory predictive models applicable to WIPP-like conditions are
10 yet available. Because the implementation of an MgO backfill limits the pmH and f_{CO_2} to
11 discrete values, empirical measurement of the solubility of U(VI) in WIPP and/or WIPP-like
12 brines became practical. As documented in Hobart and Moore (1996) and used in prior PA
13 calculations, the solubility of U(VI) at pH 10, in the absence of carbonate, was determined to be
14 8.8×10^{-6} m. This is augmented by additional data from U(VI) solubility studies in WIPP-
15 relevant carbonate-free brines reported in Section SOTERM-3.3.2 (Lucchini et al. 2009). Here,
16 the measured U(VI) solubility was 10^{-7} M to 10^{-6} M for GWB and ERDA-6 brine, respectively.

1 The solubility of U(VI) currently used in WIPP PA was established through discussions with the
2 EPA to be 1 mM (U.S. Environmental Protection Agency 2005) to account for the potential and
3 expected effects of carbonate.

4 **SOTERM-4.5 Calculations of Actinide Solubility Using the FMT Computer** 5 **Code**

6 Details of the implementation of FMT and an early version of the CHEMDAT database are
7 given in Novak (1995, Appendix D) and in the FMT User's Manual (Babb and Novak 1995 and
8 1997). FMT calculates chemical equilibrium for user-specified total element amounts in
9 aqueous or aqueous/mineral geochemical systems. The FMT calculations of actinide solubility
10 in the WIPP system performed for WIPP PA included preequilibration with halite, anhydrite,
11 brucite, and magnesite (Novak, Moore, and Bynum 1996; Novak and Moore 1996), which are
12 the minerals present in large quantities in the repository. The effects of the MgO backfill are
13 realized by equilibrating brine with brucite, magnesite, and hydromagnesite.

14 **SOTERM-4.5.1 Pitzer Approach for High-Ionic-Strength Brines**

15 The Pitzer formalism is substantially different in approach from the classic Debye-Hückel (D-H)
16 theory of the behavior of ionic solutions. The latter is a theoretical approach to describing the
17 behavior of dilute solutions; more importantly, because many ionic solutes do not behave ideally
18 even at very low concentrations, it provides a means to calculate the activity, a_i , of a desired
19 species. This is of great importance, as the Gibbs free energies of the various species in solution
20 can be used to calculate solution equilibria if one knows the effective concentration of those
21 species, i.e. their "activity" in solution. The activity of a given species i is tied to the molality of
22 that species as $a_i = \gamma_i m_i$. Since the molality of species i is known, the unknown that must be
23 calculated to determine a_i is, therefore, γ_i . The simplest form relating activity to molality from
24 the D-H law is

$$25 \quad \log \gamma_i = -A_\gamma z_i^2 \left(\frac{\sqrt{I}}{1 + \sqrt{I}} \right) \quad (\text{SOTERM.71})$$

26 where A_γ is the Debye-Hückel parameter, z_i is the charge of the i th species and I is the overall
27 solution ionic strength. The fundamental difficulty with the D-H formalism is that even with
28 extensions (Davies equation, B-dot equation), the D-H law begins to deviate significantly from
29 real solution behavior somewhere in the general region of $I = 0.3$ molal. As the WIPP brines
30 (and many other highly concentrated ionic species of interest) are well above this level of ionic
31 strength, many times with $I > 5$, another description is required to properly describe the activities
32 of the ionic species.

33 In 1973, Pitzer proposed a set of semiempirical equations to describe a_i . Pitzer (1973) wrote the
34 Gibbs excess energy of a solution as a virial expansion, where a portion of the overall expansion
35 can be tied down to a formalism similar to the D-H law and the majority of the remaining
36 constants are empirically determined from measurements of the desired ions. The most general
37 form of the equation is

$$\ln \gamma_i = \left(\frac{z_i^2}{2} \right) f'(I) + 2 \sum_j \lambda_{ij}(I) m_j + \sum_{jk} \left(\left(\frac{z_i^2}{2} \right) \lambda'_{ijk}(I) + 3 \mu_{ijk} \right) m_j m_k, \quad (\text{SOTERM.72})$$

2 where $f(I)$ is a Debye-Hückel function, $f'(I)$ is its derivative df/dI , the λ_{ij} are second-order
 3 interaction coefficients, $\lambda'_{ij}(I)$ is the derivative $d\lambda_{ij}/dI$, and the μ_{ijk} are third-order interaction
 4 coefficients. The experimentally observable values $\beta^{(0)}$, $\beta^{(1)}$, $\beta^{(2)}$, α_1 , α_2 , C^ϕ , and so forth are used
 5 to calculate the λ_{ij} and μ_{ijk} values needed to calculate γ_i (for more detail, see Wolery and Daveler
 6 1992).

7 This approach has proven highly effective and has successfully described the behavior of
 8 solutions at high ionic strength. The disadvantage of this technique is that binary and ternary
 9 coefficients for the expansion are normally needed to completely describe all the activities of the
 10 different species; in addition, if the number of species in solution grows, the number of
 11 calculations grows that much faster, i.e., on the order of the cube of the number of species. This
 12 problem would be even worse, except that many of the terms describing neutral species can be
 13 legitimately neglected in geochemical systems.

14 This parameter-determination problem is of particular interest in the description of actinide
 15 behavior in the WIPP, since the GWB and ERDA-6 brines of interest contain a wide variety of
 16 ions in and of themselves, in addition to the actinides introduced into the repository. As a result
 17 of this, it was necessary to constrain the total number of possible species in solution, aqueous,
 18 solid or gas, and in addition, to determine Pitzer parameters for many species by analogy to
 19 others rather than by experimental measurement. This is the basis of the parameter and species
 20 selection in the current database, FMT_050405.CHEMDAT, which contains the parameters (free
 21 energies, Pitzer parameters, etc.) for those species incorporated into the limited species set
 22 description. In practice, this has worked well to describe solution behavior in the WIPP within a
 23 limited set of pH values at 25 °C, but does not describe the WIPP system in all regions of
 24 interest.

25 **SOTERM-4.5.2 Calculated Actinide Solubilities**

26 The oxidation-state-specific actinide solubilities calculated with the FMT thermodynamic model
 27 are summarized in Table SOTERM-17 for the CRA-2004 PABC. For historical perspective, the
 28 calculated solubilities from prior PA analyses are tabulated in Table SOTERM-18. In the CRA-
 29 2004 PABC, the data are shown for two brines in the presence of organics, and as a function of
 30 equilibration with hydromagnesite or magnesite. The hydromagnesite case is recognized by the
 31 project as the most relevant to WIPP. It is important to note that, overall, the calculated
 32 solubilities have not changed much over time (generally within a factor of two) when organics
 33 are not considered.

1 **Table SOTERM-17. Solubilities of the Oxidation-State Analogs (M) with MgO Backfill**
 2 **Calculated for the CRA-2004 PABC (Brush 2005)**

Brine	FMT Name	Solubilities of the Actinide Oxidation States from the FMT Calculations for PABC			
		(III)	(IV)	(V)	(VI) ^a
GWB	Run 7 (hydromagnesite with organics [hmag. w orgs.])	3.87×10^{-7}	5.64×10^{-8}	3.55×10^{-7}	1×10^{-3}
ERDA-6	Run 11 (hmag. w orgs)	2.88×10^{-7}	6.79×10^{-8}	8.24×10^{-7}	1×10^{-3}
GWB	Run 5 (mag. w orgs)	3.87×10^{-7}	4.57×10^{-8}	6.59×10^{-6}	1×10^{-3}
ERDA-6	Run 9 (mag. w orgs)	2.87×10^{-7}	4.84×10^{-8}	1.08×10^{-5}	1×10^{-3}

hmag. – hydromagnesite

mag. – magnesite

^a Not calculated with the FMT model

VI, Castile brine	8.8×10^{-6}	8.8×10^{-6}	8.8×10^{-6}	8.8×10^{-6}

7

8 The calculated solubility of the III actinides was 2.87×10^{-7} M to 3.87×10^{-7} M in the CRA-2004
 9 PABC (Brush and Xiong 2005b). These data are also fairly consistent with recently measured
 10 results for Nd(III) solubility in brine (Borkowski et al. 2008). A somewhat broader range was
 11 noted historically: 1.3×10^{-8} M to 5.82×10^{-7} M. The expected solubility of the IV actinides
 12 ranges between 4.57×10^{-8} M and 6.79×10^{-8} M. This is also somewhat consistent with prior
 13 calculations (Table SOTERM-18) and has increased slightly. Overall the solubility of the IV
 14 actinides is four to eight times lower than that predicted for the III actinides. The main reason
 15 for increases noted in CRA-2004 PABC was the presence of organics in the brines.

1 Uncertainties in the solubility data and uncertainty in the NONLIN least-squares refinement, for
2 Pitzer parameter determination, result in uncertainty in the model predictions. This distribution
3 was sampled and used in PA as discussed in Section SOTERM-5.0 (Xiong, Nowak, and Brush
4 2005).

5 **SOTERM-4.6 Calculation of the Effects of Organic Ligands on Actinide** 6 **Solubility**

7 Four organic ligands are included in FMT calculations of actinide solubilities. These are acetate
8 (CH_3CO_2^-), citrate [$(\text{CH}_2\text{CO}_2)_2\text{C}(\text{OH})(\text{CO}_2)^{3-}$], EDTA [$(\text{CH}_2\text{CO}_2)_2\text{N}(\text{CH}_2)_2\text{N}(\text{CH}_2\text{CO}_2)_2^{4-}$], and
9 oxalate ($\text{C}_2\text{O}_4^{2-}$). The current projected inventory of these complexing agents, with their
10 inventory-limited solubilities in the WIPP, were summarized in Table SOTERM-5. These
11 ligands are included in the solubility calculations because (1) approximately 60 organic
12 compounds were identified among the nonradioactive constituents of the TRU waste to be
13 emplaced in the WIPP (Brush 1990; Drez 1991; U.S. Department of Energy 1996); (2) 10 of
14 these 60 organic compounds could, if present in the WIPP, increase actinide solubilities because
15 they are soluble in aqueous solutions such as WIPP brines, and because they form complexes
16 with dissolved actinides (Choppin 1988); and (3) of these 10 water-soluble organic ligands that
17 form complexes with actinides, 4 (acetate, citrate, EDTA, and oxalate) were identified in the
18 WIPP inventory (See the CCA, Appendix SOTERM, p. 96).

19 The effects of all four ligands (acetate, citrate, EDTA, and oxalate), as well as the Mg^{2+} and Ca^{2+}
20 species present in brine, were addressed in the calculations of actinide solubility for GWB and
21 ERDA-6 brine in the PABC calculations (Brush 2005). The stability constants for the complexes
22 formed by the listed ligands with Ca^{2+} were assigned the same values as the stability complexes
23 formed by these ligands with Mg^{2+} (Giambalvo 2003). Because of insufficient data these
24 calculations did not include competition from the other dissolved metals such as Fe, V, Cr, Ni,
25 copper (Cu), and Pb, all of which could be present at significant concentrations due to
26 dissolution of steels and other metallic constituents of TRU waste (see Table SOTERM-19 and
27 U.S. Department of Energy 2006). The FMT calculations (Brush 2005) demonstrate that the
28 solubility of the III and IV actinides was not significantly enhanced by complexation with
29 acetate, citrate, EDTA, and oxalate at their maximum potential concentrations (Table SOTERM-
30 19). EDTA does, however, exert a strong influence on the speciation of the III actinides, in that
31 it essentially forms a 1:1 complex with the actinide. In this context, higher levels of EDTA in
32 the repository, should they exist, could overwhelm carbonate complexation and hydrolysis to
33 dominate the speciation of the III actinides.

34 In the FMT calculations, all four ligands (acetate, citrate, EDTA, and oxalate) were present
35 simultaneously in Salado or Castile brine at the concentrations calculated by Brush and Xiong
36 (2005a). The results of the FMT calculations for the CRA-2004 PABC demonstrate that acetate,
37 citrate, EDTA, and oxalate will not form complexes with the III and IV actinides to a significant
38 extent under expected WIPP conditions, and thus will not significantly affect the III and IV
39 actinide solubilities (Brush and Xiong 2003c; Downes 2003a and 2003b).

40 The importance and role of colloids in defining the concentration of actinide in the WIPP was
41 discussed in Section SOTERM-3.8, and more extensive discussions of WIPP-related results were
42

3
 4 presented in the CRA-2004, Appendix PA, Attachment SOTERM. Results of the colloidal
 5 actinide investigation were used in the CRA-2004 PABC, the CRA-2004 PA, the CCA PA, and
 6 the 1997 PAVT to define the PA approach to accounting for colloidal enhancement of actinide
 7 concentrations. The four types of colloids identified as relevant to the WIPP are listed and
 8 described in Table SOTERM-20.

9 **Table SOTERM-20. Classification of Four Colloid Types Considered by WIPP PA**

Mineral Fragment Colloids	Hydrophobic, hard-sphere particles that are kinetically stabilized or destabilized by electrostatic forces and may consist of crystalline or amorphous solids. Mineral fragments may be made kinetically stable by coatings with steric stabilizers that prevent close contact. Mineral fragments may act as substrates for sorption of actinides, or they may consist of precipitated or coprecipitated actinide solids.
Intrinsic Actinide Colloids	Intrinsic actinide colloids (also known as true colloids, real colloids, Type I colloids, and Eigenkolloide) are macromolecules of actinides that, at least in some cases, may mature into a mineral-fragment type of colloidal particle. When immature, they are hydrophilic; when mature, they become hydrophobic.
Humic Colloids	Humic substances are hydrophilic, soft-sphere particles that are stabilized by solvation forces. They are often powerful substrates for uptake of metal cations and are relatively small (less than 100,000 atomic mass units).
Microbial Colloids	Microbes are relatively large colloidal particles stabilized by hydrophilic coatings on their surfaces, which behave as steric stabilizing compounds. They may act as substrates for extracellular actinide sorption or actively bioaccumulate actinides intracellularly.

10
 11 **SOTERM-4.7 Calculation of Colloidal Contribution to Actinide Solution**
 12 **Concentrations**

13 Three types of parameter values were determined: (1) constant concentration values, (2)
 14 concentration values proportional to the dissolved actinide concentration, and (3) maximum
 15 concentration values. The parameter types are summarized below and were initially described in
 16 parameter record packages (Papenguth and Behl 1996a; Papenguth 1996a, 1996b, and 1996c)

1 and resummarized for the CRA-2004 PABC (Garner and Leigh 2005). For intrinsic actinide
 2 colloids and mineral-fragment colloids, associated actinide concentrations were described as
 3 constant values. Table SOTERM-21 summarizes the material and parameter names and
 4 descriptions.

5 **Table SOTERM-21. Material and Property Names for Colloidal Parameters**

Material	Property	Brief Description of Parameter
Th, U, Np, Pu, Am	CONCMIN	Concentration of actinide associated with mobile mineral fragment colloids
Th, U, Np, Pu, Am	CONCINT	Concentration of actinide associated with mobile intrinsic actinide colloids
Th, U, Np, Pu, Am	PROPMIC	Proportionality constant for concentration of actinides associated with mobile microbes
PHUMOX3 ^a PHUMOX4 PHUMOX5 PHUMOX6	PHUMCIM	Proportionality constant for concentration of actinides associated with mobile humic colloids; in Castile brine; actinide solubilities are inorganic only (complexes with man-made organic ligands are not important); solubilities were calculated assuming equilibrium with Mg-bearing minerals (brucite and magnesite)
PHUMOX3 ^a PHUMOX4 PHUMOX5 PHUMOX6	PHUMSIM	Proportionality constant for concentration of actinides associated with mobile humic colloids; in Salado brine; actinide solubilities are inorganic only (complexes with man-made organic ligands are not important); solubilities were calculated assuming equilibrium with Mg-bearing minerals (brucite and magnesite)
Th, U, Np, Pu, Am	CAPMIC	Maximum (cap) concentration of actinide associated with mobile microbes
Th, U, Np, Pu, Am	CAPHUM	Maximum (cap) concentration of actinide associated with mobile humic colloids

^a Proportionality constant for actinide concentrations associated with mobile humic substances for PHUMOX3, for actinide elements with oxidation state *III* (that is, Pu(III) and Am(III)); PHUMOX4, oxidation state *IV* (Th(IV), U(IV), Np(IV), and Pu(IV)); PHUMOX5, oxidation state *V* (Np(V)); and PHUMOX6, oxidation state *VI* (U(VI)).

6
 7 Experiments conducted to quantify actinide concentrations associated with humic substances and
 8 microbes provided the basis for a more sophisticated representation, in which colloidal actinide
 9 concentrations were related to the dissolved actinide concentration by proportionality constants.
 10 For microbes, the proportionality relationship was made by element. For humic actinides,
 11 however, the relationship was made by oxidation state, rather than by element. For microbes and
 12 humic substances, the experiments also provided a basis to define upper limits of the actinide
 13 concentration that could be associated with each of those colloid types. For both humic and
 14 microbial actinides, the upper limit parameter was defined by element, rather than oxidation
 15 state, and is in units of molality. The use of the two upper limit parameters is slightly different,
 16 and is described in the sections below discussing humic substances and microbes.

17 The colloid concentration factors used in the CRA-2004 PABC are summarized in Table
 18 SOTERM-22. The general approach used to account for colloidal enhancement of actinide
 19 solubilities is described in detail by Garner and Leigh (2005). There were essentially no changes
 20 in the approach used from the CRA-2004 PA. The maximum concentrations of actinides
 21 predicted for the four types of WIPP colloids are tabulated in Table SOTERM-23. These data
 22

1 **Table SOTERM-22. Colloid Concentration Factors (The CRA-2004, Appendix PA,**
 2 **Attachment SOTERM)**

Actinide	CONCMIN (Concentration on Mineral Fragments ^a)	CONCINT (Concentration as Intrinsic Colloid ^a)	PROPMIC (Proportion Sorbed on Microbes ^{b,c})	CAPMIC (Maximum Sorbed on Microbes ^d)	Proportion Sorbed on Humics ^b		CAPHUM (Maximum Sorbed on Humics ^a)

6
 7 show that microbial colloids are likely to have the most significant effect on actinide
 8 concentrations, with a smaller but significant contribution from the humic colloidal fraction.
 9 Section SOTERM-5.0 provides more details on the PA implementation of these data.

1 **SOTERM-5.0 Use of the Actinide Source Term in PA**

2 The WIPP ASTP provided the parameters to construct the maximum dissolved and suspended
3 colloidal actinide concentrations for use in modeling the mobilization and transport of actinides
4 in the disposal system. In the WIPP PA, mobilization of radionuclides is represented by the
5 PANEL code and transport of radionuclides within the repository and the Salado is represented
6 by the Nuclide Transport System (NUTS) code (Appendix PA-2009, Section PA-4.4 and Section
7 PA-4.3, respectively). A description of the simplifications, manipulations, and approach used in
8 the PA to perform this modeling is discussed in this section.

9 **SOTERM-5.1 Simplifications**

10 The DOE has concentrated on those processes most likely to have a significant impact on system
11 performance. Therefore, several simplifications were used in the modeling of radionuclide
12 mobilization and transport in the CCA PA, the CCA PAVT, the CRA-2004 PA, the CRA-2004
13 PABC, and the CRA-2009 PA calculations. These include

- 14 • Using constant solubility parameters and constant colloidal parameters throughout the
15 repository and regulatory period for a given realization
- 16 • Modeling only the isotopes most important to compliance
- 17 • Using the compositions of Castile and Salado brines (the end-member brines) to bracket the
18 behavior of mixtures of these brines within the repository
- 19 • Sampling only the uncertain parameters with the most significant effect on repository
20 performance
- 21 • Combining dissolved and colloidal species for transport within the disposal system, as
22 modeled by NUTS and PANEL

23 **SOTERM-5.1.1 Elements and Isotopes Modeled**

24 Selection of isotopes for modeling mobilization and transport in the disposal system with NUTS
25 and PANEL is described in Appendix PA-2009, Section PA-4.3.3. Runs of PANEL, the PA
26 code that computes total mobilized radionuclide concentrations, include 29 radionuclides in the
27 decay calculations (Garner and Leigh 2005, Table 7 and Table 12). Runs of NUTS, the PA code
28 that computes radionuclide transport within the Salado, are based on five radionuclides: (²³⁰Th,
29 ²³⁴U, ²³⁸Pu, ²³⁹Pu, and ²⁴¹Am) that represent groupings of radionuclides with similar decay and
30 transport properties (Appendix PA-2009, Section PA-4.3.3). The number of radionuclides for
31 transport calculations in NUTS has been reduced because calculations for the full WIPP
32 inventory and decay chains would be very time consuming and because accurate results can be
33 achieved with this limited set of radionuclides.

34 Transport calculations in the Culebra use a reduced set of four radionuclides: (²³⁰Th, ²³⁴U, ²³⁹Pu,
35 and ²⁴¹Am) for computational efficiency (Garner 1996). ²³⁸Pu has been omitted from transport in

1 the Culebra because its short half-life (87.7 years) means that little ²³⁸Pu will enter the Culebra
 2 via brine flows up a borehole.

3 **SOTERM-5.1.2 Use of Brine End Members**

4 The general scenarios described in Appendix PA-2009, Section PA-2.3.2 and Section PA-3.10
 5 and considered in the source term calculations may be categorized into three groups: (1)
 6 undisturbed performance (BRAGFLO S1 scenario); (2) intrusion through the repository and into
 7 the Castile, intersecting a pressurized brine reservoir (BRAGFLO S2, S3, and S6 scenarios); and
 8 (3) intrusion through the repository, but not into a pressurized brine reservoir (BRAGFLO S4
 9 and S5 scenarios). The specific scenarios and the associated type of borehole intrusion
 10 considered by the WIPP PA are listed in Table SOTERM-24.

11 **Table SOTERM-24. WIPP PA Modeling Scenarios for the CRA-2004 PABC (Garner and**
 12 **Leigh 2005; Leigh et al. 2005)**

BRAGFLO Scenario	Description	Brine Used in PA
S1	E0 (Undisturbed Repository)	Salado (GWB)
S2	E1 intrusion at 350 years penetrates the repository and a brine pocket	Castile (ERDA-6)
S3	E1 intrusion at 1000 years penetrates the repository and a brine pocket	Castile (ERDA-6)
S4	E2 intrusion at 350 years penetrates the repository (only)	Salado (GWB)
S5	E2 intrusion at 1000 years penetrates the repository (only)	Salado (GWB)
S6	E2 intrusion at 1000 years penetrates the repository (only); E1 intrusion at 2000 years penetrates the repository and a brine pocket	Castile (ERDA-6)

13
 14 Brine may enter the repository from three sources, depending on the nature of the borehole
 15 intrusion. Under all scenarios, brine may flow from the surrounding Salado through the DRZ
 16 and into the repository in response to the difference between the hydraulic head in the repository
 17 and in the surrounding formation. For the BRAGFLO S2 through S6 scenarios, in which a
 18 borehole is drilled into the repository, brine may flow down the borehole from the Rustler and/or
 19 the Dewey Lake. For the BRAGFLO S2, S3, and S6 scenarios, in which a pressurized Castile
 20 brine reservoir is intercepted, brine from the Castile may flow up the borehole into the
 21 repository.

22 As mentioned in Section SOTERM-2.3.1, the brines in the Salado and Castile have different
 23 compositions and the actinides solubilities are somewhat different in each of these end-member
 24 compositions.

1 The composition of the more dilute groundwaters from the Rustler and Dewey Lake are expected
2 to change rapidly upon entering the repository as a result of fast dissolution of host Salado
3 minerals from the walls and floor of the repository. These minerals comprise about 90-95%
4 halite and about 1-2% each of polyhalite, gypsum, anhydrite, and magnesite (Brush 1990).
5 Calculations titrating Salado rock into dilute brines using EQ3/6 (Wolery 1992; Wolery and
6 Daveler 1992) show that gypsum, anhydrite, and magnesite saturate before halite. When halite
7 saturates, the brine composition is very similar to that of Castile brine. One hundred times as
8 much polyhalite must be added to the system before the resulting brine has a composition similar
9 to Salado brines. These calculations indicate that if dilute brines dissolve away only the surfaces
10 of the repository, they will obtain Castile-like compositions, but if they circulate through the
11 Salado after saturating with halite, they may obtain compositions similar to Salado brine.
12 Similarly, if Castile brine circulates through enough host rock, it may also approach Salado brine
13 composition. In either case, the actual brine within the repository may be described as a mixture
14 of the two concentrated-brine end members: Salado and Castile. This mixture, however, is very
15 hard to quantify, because it is both temporally and spatially variable. Only in the undisturbed
16 scenario is the mixture well defined as 100% Salado brine over the 10,000-year regulatory
17 period. In this context, the Salado (GWB) and Castile (ERDA-6) brines bracket the range of
18 expected brine compositions.

19 For a panel intersected by a borehole, the BRAGFLO calculations show that in the 10% of the
20 repository represented by the BRAGFLO panel computational cells, the ratio of brine inflow that
21 enters through the borehole versus through inflow from the host rock varies in time and depends
22 on the sampled parameter values and scenario considered. This ratio was the only measure of
23 brine mixing available to the source term runs in the CCA PA, the CCA PAVT, the CRA-2004
24 PA, and the CRA-2004-PABC calculations. As an estimate, this ratio (1) does not account for
25 compositional changes that occur when H₂O is consumed by corrosion reactions; (2) does not
26 resolve the details of flow, diffusion, and brine interaction with internal pillars and the DRZ; and
27 (3) is an average over one-tenth of the repository. It is expected that the fraction of Salado brine
28 will be quite high in areas of the repository distant from the borehole and much lower near the
29 borehole. Because radionuclide travel up the borehole can lead to significant release, the
30 solubility of radionuclides near the borehole is important. Given these uncertainties, the DOE
31 decided to use the Castile end-member composition to calculate radionuclide solubilities for
32 scenarios where a borehole penetrates a brine reservoir, and to use the Salado end-member
33 composition for scenarios where it does not (see Table SOTERM-24).

34 **SOTERM-5.1.3 Sampling of Uncertain Parameters**

35 The parameters to be sampled for the PA were selected based on the expected significance of
36 their effect on repository performance. The following four parameters are sampled
37 independently (Garner and Leigh 2005, Table 3 and Table 8):

- 38 • The solubility uncertainty for oxidation state III (see discussion below and Figure SOTERM-
39 19).
- 40 • The solubility uncertainty for oxidation state IV (see discussion below and Figure SOTERM-
41 20).

1
2 **Figure SOTERM-19. Frequency Distribution of the Deviation of Experimental log**
3 **Solubility from Model-Predicted Value for all An(III) Comparisons.**
4 **A Total of 243 Measured and Predicted Solubilities were Compared**
5 **(Xiong 2005).**

- 6 • The oxidation state for Pu, Np, and U. The sampled value is a flag that is “low” 50% of the
7 time and “high” 50% of the time. If the flag is set to “high,” Pu is assumed to be in the IV
8 oxidation state, Np is assumed to be in the V oxidation state, and U is assumed to be in the
9 VI oxidation state. If the flag is set to “low,” Pu is assumed to be in the III oxidation state
10 and Np and U are assumed to be in the IV oxidation state.
- 11 • The humic-acid proportionality constant for the III oxidation state in Castile brine (see Table
12 SOTERM-22 and Figure SOTERM-21).

13 As discussed by Garner and Leigh (2005, Section 2.3), the solubility uncertainty for oxidation
14 state V is zero. The solubility uncertainty for oxidation state VI is zero because the EPA
15 specified a fixed, maximum solubility of 1×10^{-3} mol/L for U(VI).

16 Actinide solubilities for a single realization in the PA depend on (1) the oxidation state; (2) the
17 brine for that realization (see Table SOTERM-24); and (3) the solution concentration
18 uncertainty, as shown in Equation (SOTERM.73).

1
 2 **Figure SOTERM-20. Frequency Distribution of the Deviation of Experimental log**
 3 **Solubility from Model-Predicted Value for all An(IV) Comparisons.**
 4 **A Total of 45 Measured and Predicted Solubilities were Compared**
 5 **(Xiong 2005).**

6
$$C_{i,b} = (S_{i,b}) \times (10^{SU_i}) \quad \text{(SOTERM.73)}$$

7 $C_{i,b}$, used for every element in oxidation state i , is the concentration of oxidation state i and brine
 8 b . $S_{i,b}$ is the solubility calculated for oxidation state i in brine b with FMT (see Table SOTERM-
 9 17). SU_i is the solubility uncertainty sampled from a distribution unique to each oxidation state.
 10 Figure SOTERM-19 shows the distribution of SU values for oxidation state III. Figure
 11 SOTERM-20 shows the distribution of SU values for oxidation state IV. These distributions are
 12 calculated and documented in Xiong (2005).

13 Figure SOTERM-21 shows the cumulative distribution function for the humic-acid
 14 proportionality constant.

1

2 **Figure SOTERM-21. Cumulative Distribution Function for the Humic-Acid**
 3 **Proportionality Constant**

4 **SOTERM-5.1.4 Combining the Transport of Dissolved and Colloidal Species**
 5 **in the Salado**

6 Dissolved and colloidal species may transport differently because of different diffusion rates,
 7 sorption onto stationary materials, and size-exclusion effects (filtration and hydrodynamic
 8 chromatography). With maximum molecular diffusion coefficients of about $4 \times 10^{-10} \text{ m}^2/\text{s}$,
 9 actinides are estimated to diffuse about 10 m in 10,000 years, a negligible distance. Sorption and
 10 filtration have beneficial but unquantified effects on performance. Hydrodynamic
 11 chromatography may increase colloidal transport over dissolved transport by, at most, a factor of
 12 two for theoretically perfect colloidal-transport conditions. In the WIPP, the expected increase is
 13 much lower. Given the small or beneficial nature of these effects, they were not included in the
 14 CCA PA, the CCA PAVT, the CRA-2004 PA, or the CRA-2004 PABC calculations of
 15 radionuclide transport in the repository.

16 **SOTERM-5.2 Construction of the Source Term**

17 Because there was no modeled mechanism in PA to differentiate dissolved from colloidal
 18 species, the DOE combined them for transport within the Salado. To model transport within the
 19 Culebra, however, this simplification was replaced by separating the mobilized actinides
 20 delivered to the Culebra by Salado transport codes into five components (dissolved, humic,

1 microbial, mineral-fragment, and intrinsic colloids) to account for differences in their transport
2 behavior. This is important because transport within the repository occurs through, at most,
3 hundreds of meters of poorly defined waste undergoing decomposition, whereas transport
4 through the Culebra occurs over kilometers in a relatively homogeneous (compared to waste)
5 fractured dolomite.

6 The parameters required to construct the source term were as follows:

- 7 1. Solubilities for four oxidation states in Salado and Castile brines, the two brine end members.
- 8 2. Uncertainty distributions to be applied to the median solubilities for oxidation states III and
9 IV.
- 10 3. A scheme for assigning sampled oxidation states (“low” or “high”).
- 11 4. Colloidal concentrations or proportionality constants for each actinide (Th, U, Np, Pu, and
12 Am) and an associated oxidation state for each of four colloid types.
- 13 5. Caps on the actinide concentrations that may be applied to two types of colloids (microbial
14 and humic).
- 15 6. Cm is assigned the source term calculated for Am.

16 Cm and Np are not explicitly transported in NUTS (see Section SOTERM-5.1.1) although they
17 are implicitly lumped with other modeled isotopes. They are, however, included in the PANEL
18 calculations for use with the DBR calculations in PA.

19 These parameters are combined into a single maximum concentration for each modeled actinide
20 in the PA calculations. The term “total mobilized concentration” is used for the combined
21 concentrations of dissolved and colloidal species. The combined concentrations are not
22 necessarily the actual concentrations, because the concentration may be lower as a result of
23 inventory limits. Both NUTS and PANEL assume that the actinide concentrations specified by
24 the total mobilized concentrations are attained instantaneously as long as sufficient inventory is
25 available. When the inventory is insufficient, the actual mobilized concentration will be lower
26 and is said to be inventory limited. The calculation of the total mobilized concentration is
27 performed by PANEL for each of 100 sampled vectors in a replicate. A similar methodology to
28 generate the combined maximum concentrations was also used for the CCA PA, the CCA
29 PAVT, the CRA-2004 PA, and the CRA-2004 PABC.

30 All of the source term parameters and their associated distributions are entered into the PA
31 parameter database. For each sampled parameter, the Latin Hypercube Sampling code uses the
32 distribution from the PA parameter database to create 100 sampled values. These values are
33 combined with the parameters that have constant values and stored in computational databases
34 for each of the 100 vectors (i.e., 100 realizations), which constitute one replicate. For each
35 realization, PANEL uses both the constant and sampled values for all of the source term
36 parameters, and constructs the source term for NUTS and PANEL, as shown below. This
37 process is repeated for scenarios using the Salado end-member total mobilized concentration and
38 for scenarios using the Castile end-member total mobilized concentration.

1 Dissolved = Base Solubility $\times 10^{\text{Sampled from Solubility Distribution}}$ (SOTERM.74)

2 IF (Dissolved \times Proportionality Constant < Humic Cap),
 3 THEN Humic = Dissolved \times Proportionality Constant, (SOTERM.75)
 4 ELSE Humic = Humic Cap

5 IF (Total Mobile < Microbial Cap),
 6 THEN Microbial = Dissolved \times Proportionality Constant, (SOTERM.76)
 7 ELSE Microbial = Microbial Cap

8 Mineral = Database Concentration (a constant value) (SOTERM.77)

9 Intrinsic = Database Concentration (a constant value) (SOTERM.78)

10 Total Mobile = Dissolved + Humic + Microbial + Mineral + Intrinsic (SOTERM.79)

11 For actinides with more than one oxidation state, the oxidation state is specified by the oxidation-
 12 state parameter

13 IF (OXSTAT ≤ 0.5); THEN Lower Oxidation State,
 14 ELSE Higher Oxidation State (SOTERM.80)

15 where OXSTAT is the oxidation-state parameter sampled from a uniform distribution between 0
 16 and 1.

17 Similar solubility calculations are performed for Am, U, Th, and Np. The total mobilized
 18 concentration and mobile fractions for Cm are set equal to the values for Am. In addition, the
 19 PA groups radioisotopes with similar decay and transport properties for the NUTS and
 20 SECOTP2D (component radionuclide transport in fractures or granular aquifers) transport
 21 calculations, as explained in Section SOTERM-5.1.1. For example, the U solubility is decreased
 22 to account for the shared solubility with the low-activity ^{238}U , which is not explicitly modeled,
 23 enabling NUTS to properly represent the effect of the U isotopes on compliance using the single
 24 lumped isotope ^{234}U (the CRA-2004, Appendix PA, Section PA-4.3.3).

25 PANEL also calculates the fraction of each actinide mobilized by the five different mechanisms,
 26 as follows:

27 Fraction dissolved = Dissolved/Total Mobilized Concentration (Conc.) (SOTERM.81)

28 Fraction on humics = Humic/Total Mobilized Conc. (SOTERM.82)

29 Fraction in/on microbes = Microbe/Total Mobilized Conc. (SOTERM.83)

30 Fraction on mineral fragments = Mineral/Total Mobilized Conc. (SOTERM. 84)

31 Fraction as intrinsic colloid = Intrinsic/Total Mobilized Conc. (SOTERM.85)

1 **SOTERM-5.3 Example Calculation of Actinide Solubility**

2 For example, for one realization in Salado brine, the sampled value for OXSTAT was 0.9, so Pu
3 would be present in the IV state. The sampled value of the solubility uncertainty distribution
4 was 1.8 for the IV state, which has a median brine solubility of 5.64×10^{-8} M. The humic
5 proportionality constant for the IV oxidation state in Salado brine is 6.3, the microbial
6 proportionality constant for Pu is 0.3, the humic cap is 1.1×10^{-5} M, the microbe cap for Pu is
7 6.8×10^{-5} M, the concentration of the actinide on mineral fragments is 2.6×10^{-8} M, and the Pu
8 intrinsic-colloid concentration is 1×10^{-9} M.

9 For this realization, the maximum dissolved concentration of Pu(IV) used by the PA would be

$$10 \quad C_{Pu} = (5.64 \times 10^{-8}) \times (10^{1.8}) = 3.6 \times 10^{-6} \text{ M.} \quad (\text{SOTERM.86})$$

11 (The calculations for this example have been rounded to two significant figures, although the PA
12 would not round the intermediate or final values.) C_{Pu} is the maximum dissolved concentration
13 of all combined isotopes of Pu.

14 The maximum humic-complexed Pu would be

$$15 \quad (3.6 \times 10^{-6} \text{ M})(6.3 \text{ mol adsorbed per mol}) = 2.3 \times 10^{-5} \text{ M.} \quad (\text{SOTERM.87})$$

16 This value, however, exceeds the cap for humic-mobilized Pu, 1.1×10^{-5} M. Therefore, in this
17 case, the cap would be used for the maximum humic-mobilized actinide concentration. Note that
18 the humic-mobilized concentration of Pu exceeds the maximum dissolved concentration of Pu,
19 which is usually the case.

20 The maximum microbial-mobilized Pu would be

$$21 \quad (3.6 \times 10^{-6} \text{ M})(0.3 \text{ mol bioaccumulated per mol}) = 1.1 \times 10^{-6} \text{ M.} \quad (\text{SOTERM.88})$$

22 This value is less than the cap, 6.8×10^{-5} M, so the cap does not affect microbial-mobilized Pu
23 for this realization.

24 The total mobilized concentration of Pu(IV) for this realization would then be the sum of the
25 dissolved and colloidal contributions (see Equation [SOTERM.79]):

$$26 \quad \text{Total Mobile} = \text{Dissolved} + \text{Humic} + \text{Microbial} + \text{Mineral} + \text{Intrinsic}, \quad (\text{SOTERM.89})$$

$$27 \quad = 3.6 \times 10^{-6} + 1.1 \times 10^{-5} + 1.1 \times 10^{-6} + 2.6 \times 10^{-8} + 1.0 \times 10^{-9},$$

$$28 \quad = 1.6 \times 10^{-5} \text{ M.}$$

29 **SOTERM-5.4 Calculated Dissolved, Colloidal, and Total Actinide Solubilities**

30 The output of the PANEL calculations is a computational database containing the source term
31 and effective inventories. NUTS and PANEL both assume instantaneous dissolution and
32 colloidal mobilization up to the solubility limits when sufficient inventory is present, as
33 discussed in Appendix PA-2009, Section PA-4.3. Table SOTERM-25 shows the dissolved and
