1 **APPENDIX WRAC**

2 This analysis discusses the techniques that could be applied in removing transuranic (TRU)
3 waste from the Waste Isolation Pilot Plant (WIPP) repository after disposal. Title 40 Code of
4 Federal Regulations (CFR) § 191.02(l) defines disposal of waste in a mined geologic
5 repository as occurring “. . .when all of the shafts to the repository are backfilled and sealed.”
6 This report will serve to document compliance with the requirement in 40 CFR § 191.14(f)
7 that the disposal system not preclude “. . .removal of most of the waste . . .for a reasonable
8 period of time after disposal.” The removal discussion is based on currently available
9 technologies. The reasoning for waste removal is not considered relevant except that it is
10 assumed the destination and transportation mechanism for the removed waste will be known.
11 Transportation methods, end use, and destinations of the removed waste are not considered in
12 this analysis.

13 **WRAC.1 WIPP Mission Description**

14 The WIPP is a research and development facility of the U.S. Department of Energy (DOE)
15 designed to demonstrate the safe transportation, handling, and disposal of defense-generated
16 TRU radioactive waste. The facility is located 26 miles (42 kilometers) east of Carlsbad, New
17 Mexico. The repository is located in a salt deposit, 2,150 feet (655 meters) below ground.
18 The waste will be shipped to the facility from numerous generator sites around the United
19 States and placed in the underground repository for disposal. Figure WRAC-1 details the
20 WIPP location and Figure WRAC-2 contains a diagram of the WIPP surface and underground
21 facilities. The facility is scheduled to begin disposal operations in 1998. A comprehensive
22 description of the WIPP disposal system is presented in Chapter 2.0. A description of the
23 *planned operation and closure of the facility is in Chapter 3.0. The waste is described in*
24 *Chapter 4.0.*

25 **WRAC.2 Analytical Scope**

26 This analysis examines the feasibility of removing emplaced waste from the WIPP repository
27 after closure. The regulatory and technical bases for removal are discussed. The
28 *emplacement and closure scenarios are defined to describe the condition of the repository and*
29 *waste after closure. The sequence of steps for removal are described including a detailed*
30 *discussion of their implementation. Since today's equipment is used to mine materials*
31 *deposited millions or billions of years ago, it is technically feasible to remove the waste*
32 *anytime during the regulatory time frame. The feasibility of waste removal is demonstrated*
33 *by describing a method for waste removal.*

34 For the purposes of this feasibility analysis, it is important to distinguish the difference
35 between waste removal and waste retrieval. Waste removal differs from waste retrieval in
36 that removal refers to actions taken after the repository is closed and sealed. Retrieval, which
37 is essentially the reverse of emplacement, refers to recovering the waste prior to waste panel
38 closure. This analysis specifically deals with waste removal.

WRAC.3 Regulations Applicable to This Feasibility Analysis

As an assurance requirement in 40 CFR Part 191, waste removal is one of several cautious steps that are to be taken to reduce the problems caused by the uncertainties inherent in the long-term predictions of disposal system performance. The EPA believes that recovery of the waste, though not necessarily easy or inexpensive, would be prudent in the event some future discovery or insight made it clear that the wastes needed to be relocated. The EPA provides specific insights regarding the implementation of this requirement as well as criteria in 40 CFR Part 194 for judging the adequacy of the DOE's demonstration of compliance to this requirement. Each is discussed below.

WRAC.3.1 40 CFR Part 191 Requirements

40 CFR § 191.14(f) states, "Disposal systems shall be selected so that removal of most of the waste is not precluded for a reasonable period of time after disposal". With respect to the recovery of waste after disposal, the preamble to 40 CFR Part 191 (50 *Federal Register* (FR) 38082) states that

...any current concept for mined geologic repository meets this requirement without any additional procedures or design features. For example, there is no intent to require that the repository shafts be kept open to allow future recovery. To meet this assurance requirement, it only need be technically feasible (assuming current technology levels) to be able to mine the sealed repository and recover the waste - albeit at substantial cost and occupational risk" (EPA 1985).

WRAC.3.2 40 CFR Part 194 Certification Criteria

40 CFR § 194.36 states that

Any compliance application shall include documentation which demonstrates that removal of waste is feasible for a reasonable period of time after disposal. Such documentation shall include an analysis of the technological feasibility of mining the sealed disposal system, given technology levels at the time a compliance application is prepared.

By way of guidance for the requisite analysis referenced in the criterion, the EPA has provided a specific list of expectations in its Compliance Application Guidance (CAG) (EPA 1996). In the CAG, the EPA states:

EPA expects the required analysis to include:

- a sequence of procedures or steps which would need to be accomplished in order for waste to be removed from the disposal system after closure;
- a discussion of how the sequence described above could be implemented, including descriptions of how currently available equipment and technologies could be utilized; and

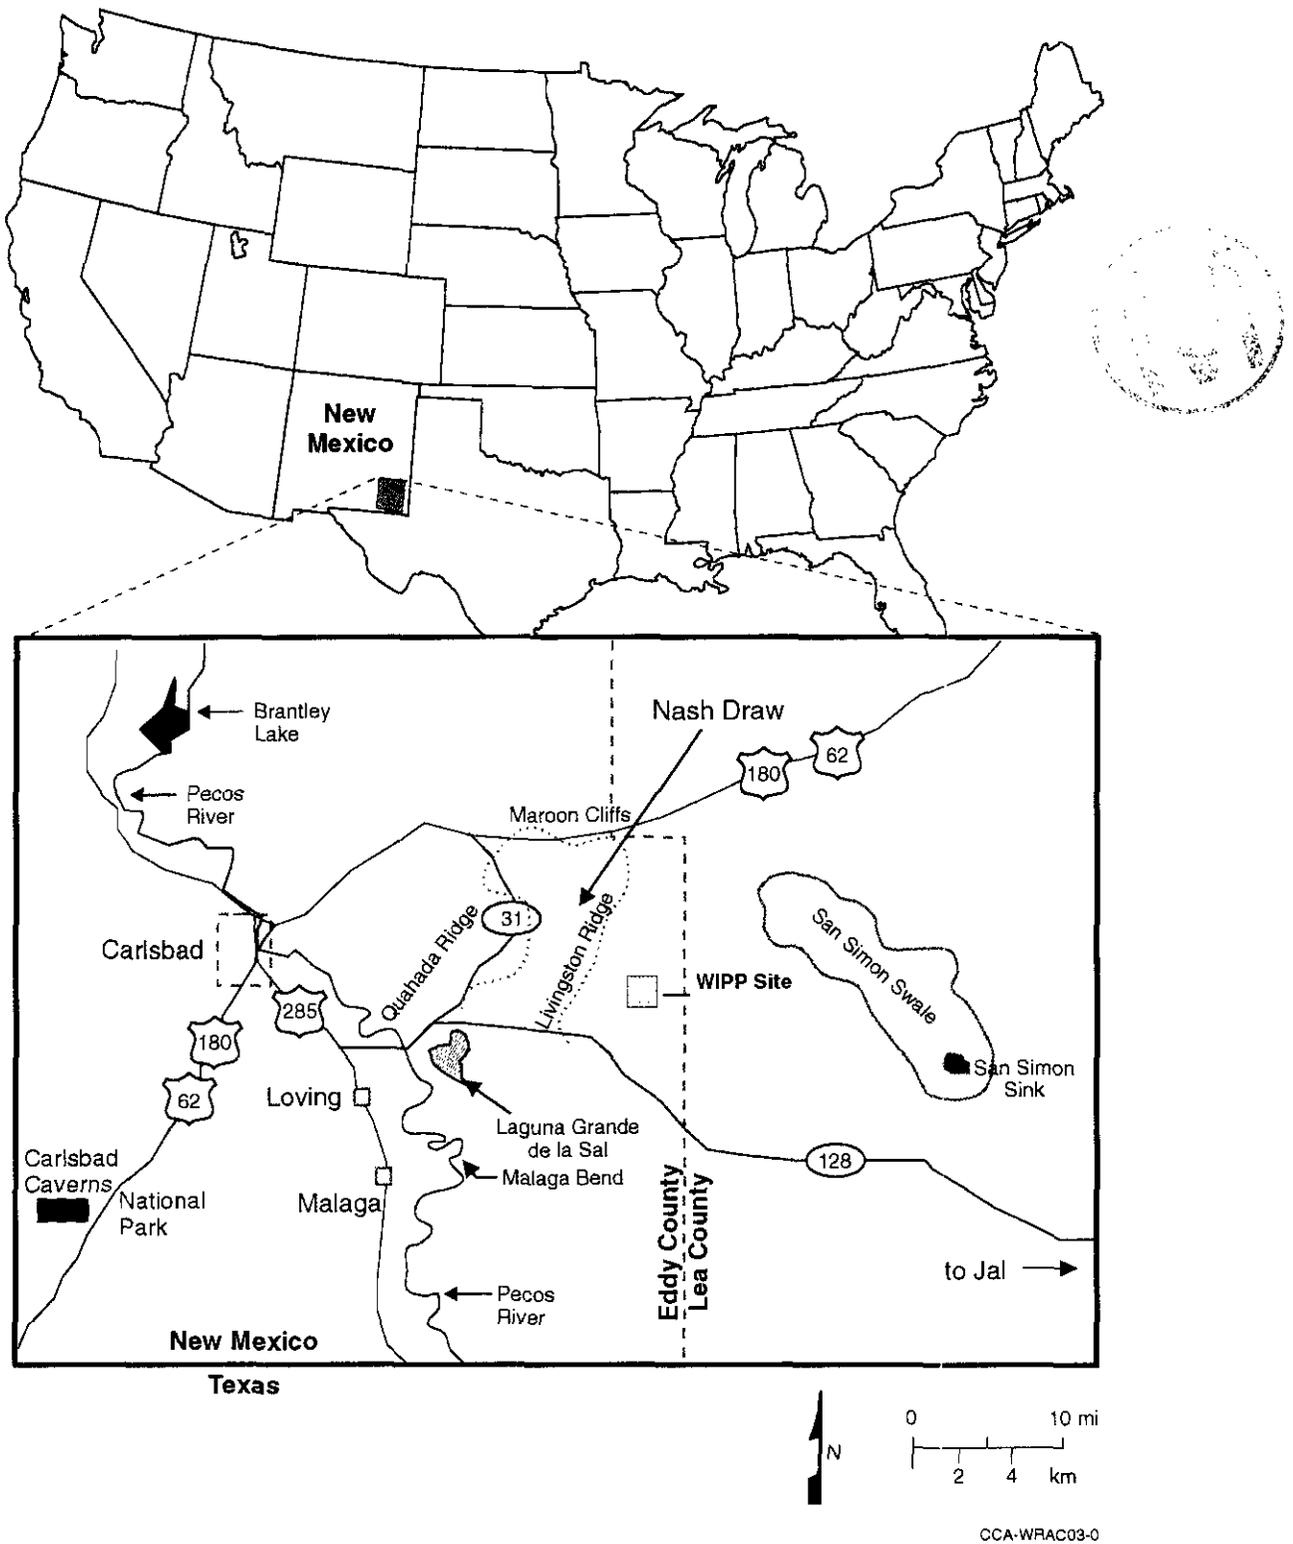

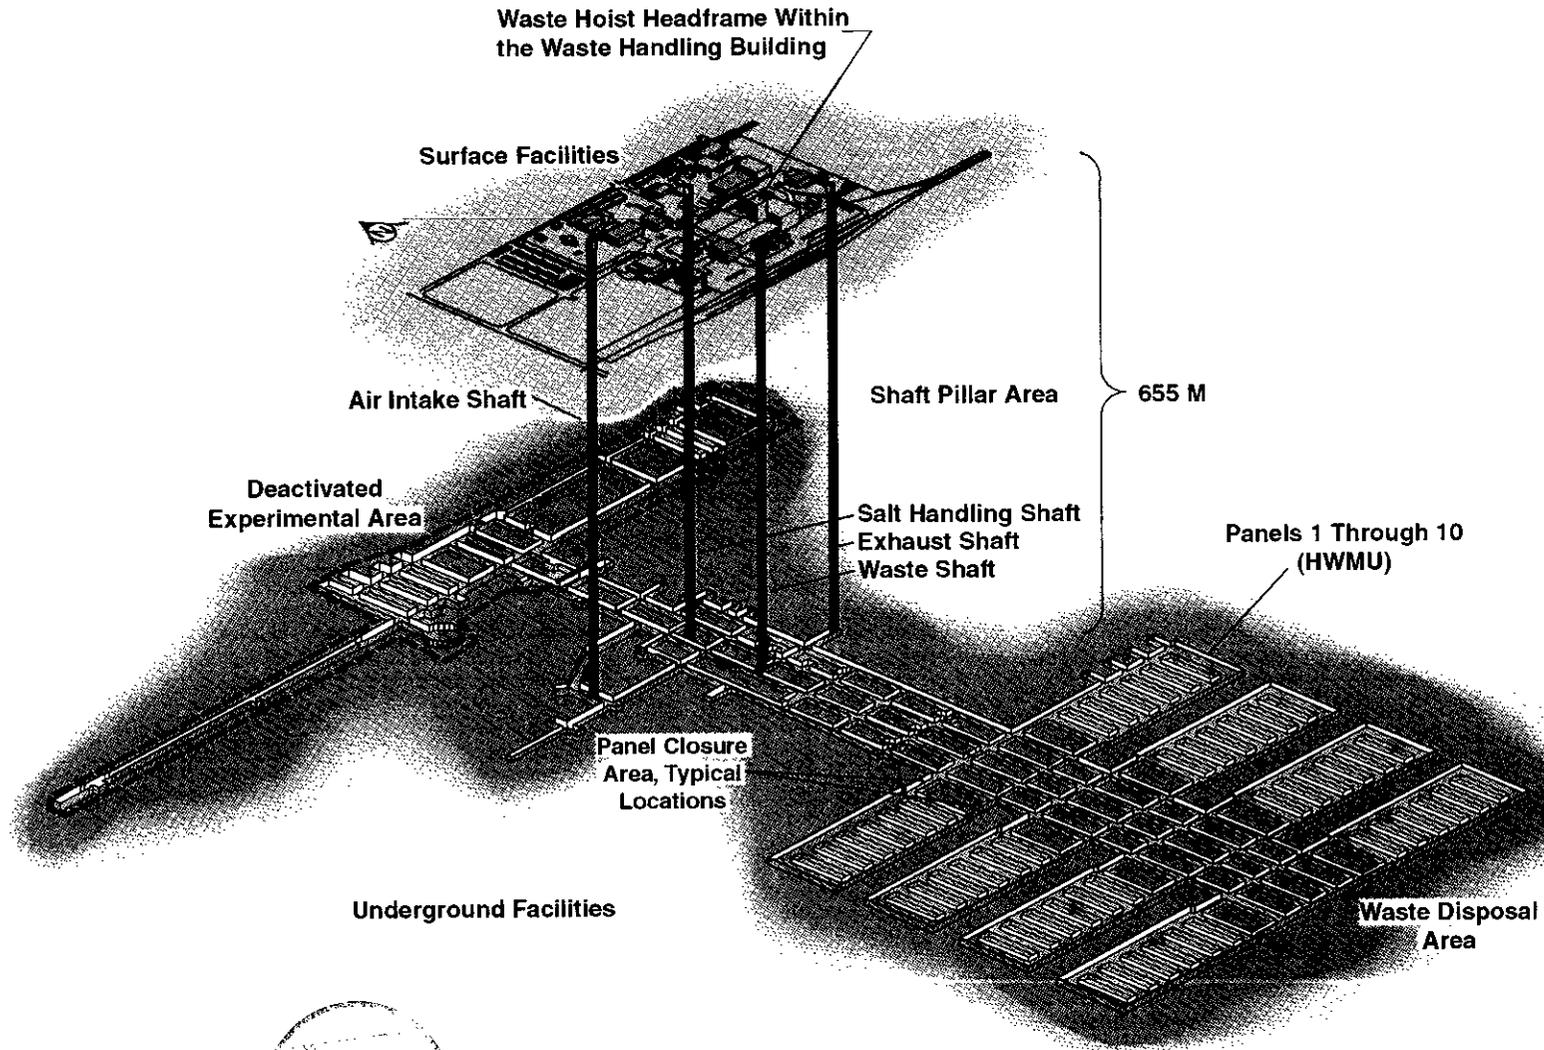

Figure WRAC-1. General Location of the WIPP Facility

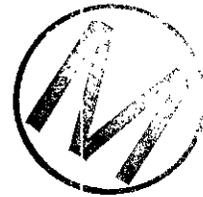

THIS PAGE INTENTIONALLY LEFT BLANK

CCA-WRAC13-0

Figure WRAC-2. WIPP Surface and Underground Facilities

THIS PAGE INTENTIONALLY LEFT BLANK

- an estimate of how long after disposal it would be technologically feasible to remove the waste, based on the disposal system design and closure, and using the system and equipment described in the application. (EPA 1996, 66)

The following feasibility analysis examines and addresses this criterion and the implementation guidance. Background information is provided as part of the feasibility analysis. This background information includes a description of the disposal system and the waste at the time of disposal and the assumed condition at the time of removal (to the practicable extent to which this condition can be anticipated).

WRAC.4 WIPP Repository Description

The WIPP will dispose of TRU waste in rooms 2,150 feet (655 meters) below the surface. These rooms are mined in a bedded halite (salt) layer known as the Salado Formation (hereafter referred to as the Salado). The Salado is approximately 2,000 feet (610 meters) thick at the repository location. Figure WRAC-3 shows the general geologic cross section of the WIPP site. *The underground repository is mined on one contiguous working level.* With the exception of the shafts and sumps, no excavations are located above or below this level. The waste will be emplaced in eight panels, each panel composed of seven rooms, and the inter-connecting access entries (drifts) identified as Panels 9 and 10. The rooms are mined to the initial dimensions of 300 feet long by 33 feet wide by 13 feet high (91 meters by 10 meters by 4 meters). The repository layout is shown in Figure WRAC-4. The waste will be emplaced in the shaded areas of Figure WRAC-4.

The waste will be composed of radioactive and hazardous waste materials generated by the DOE's nuclear weapons programs. The materials are primarily laboratory and production equipment such as glassware, solidified spent solvents, cleaning rags, laboratory clothing, solidified sludges, metal tools, pipes, plastics, and paper. TRU waste is defined as waste contaminated with alpha emitting radionuclides having atomic numbers greater than 92, half-lives greater than 20 years, and a specific activity greater than 100 nanocuries per gram. Some of the waste to be disposed of at WIPP will contain hazardous constituents as defined by the Resource Conservation and Recovery Act (RCRA). This waste is referred to as TRU mixed waste. The waste is currently generated or stored at numerous sites in the United States.

There are two classifications for the TRU waste, contact-handled (CH) TRU and remote-handled (RH) TRU. The CH-TRU waste is defined as TRU waste packaged in containers whose maximum surface dose rate does not exceed 200 millirem per hour. Surface dose rates greater than 200 millirem per hour are classified as RH-TRU waste. For emplacement into the WIPP the RH-TRU surface dose rates cannot exceed 1,000 rems per hour with a maximum total of five percent of the canisters exceeding 100 rems per hour. The total maximum activity for RH-TRU waste at WIPP cannot exceed 5.1 million curies. These limits including a maximum TRU waste volume of 6,200,000 cubic feet (175,588 cubic meters) are established by the Land Withdrawal Act (LWA).

1 The high radiation associated with RH-TRU waste is due to the presence of isotopes of
2 cesium, strontium, barium, plutonium, and yttrium. The longest half-life among these
3 isotopes is 30.0 years. Therefore, after about 300 years, the isotopes will have gone through a
4 minimum of 10 half-lives and their radioactivity, relative to the longer lived isotopes
5 associated with the CH-TRU waste, will be significantly diminished. For this reason, in
6 discussion of the removal of waste after 300 years, the DOE does not distinguish between the
7 RH-TRU and CH-TRU types.

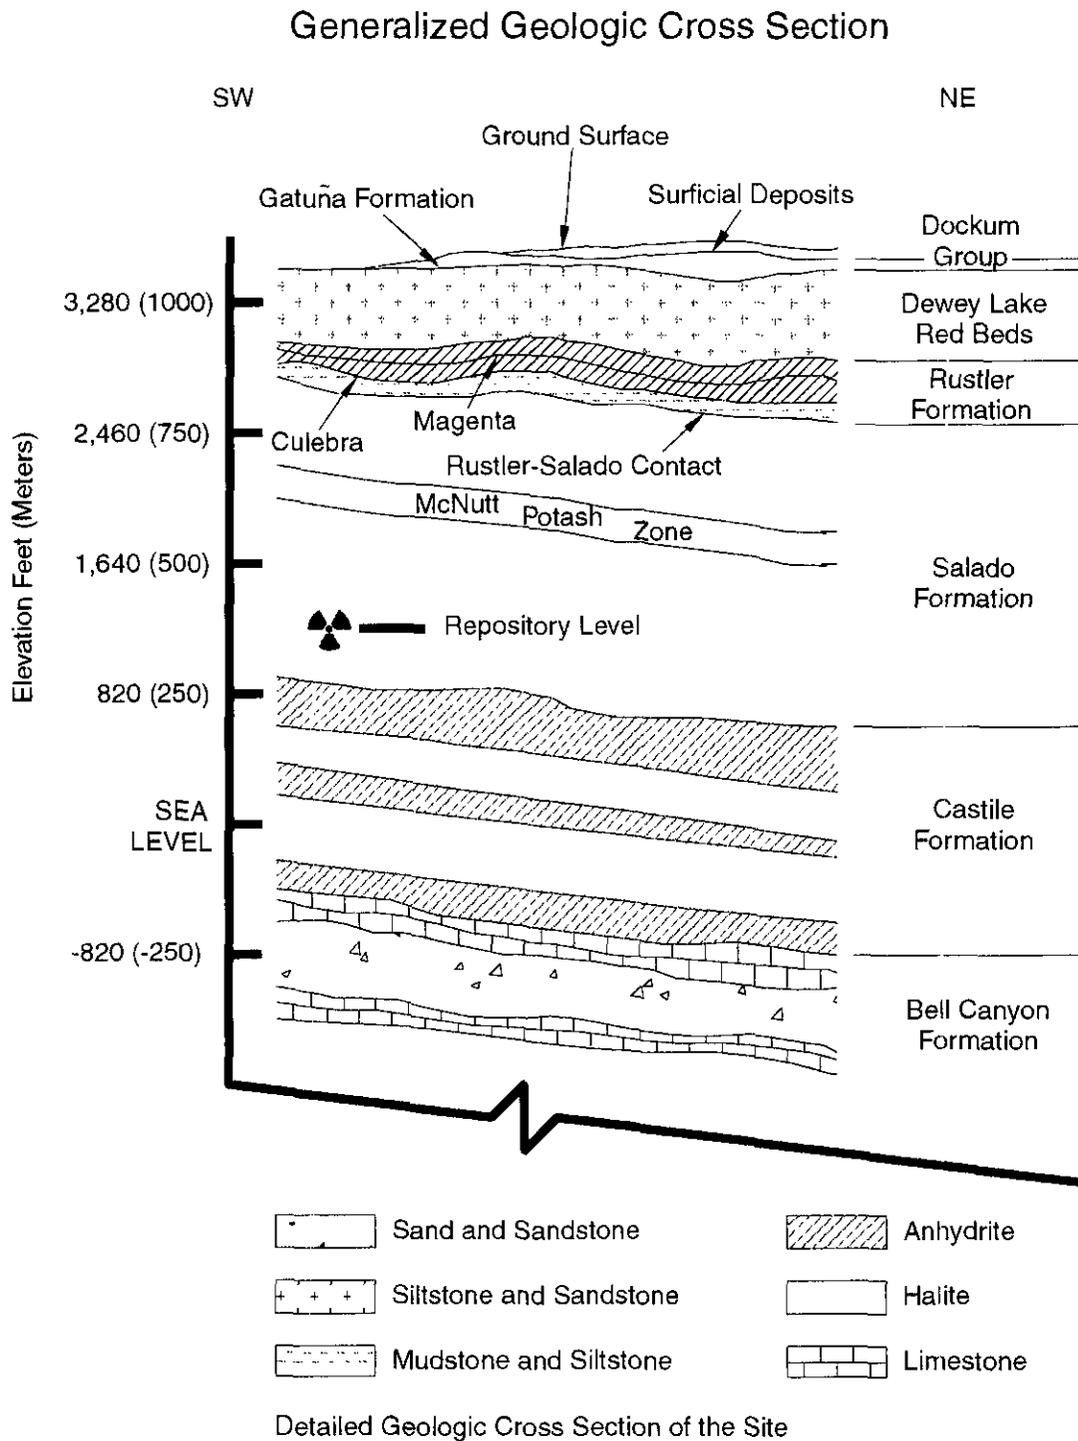

8 It is anticipated that a majority of CH-TRU waste will be shipped to the WIPP in either
9 55-gallon (208 liter) drums or standard waste boxes (SWBs). The 55-gallon drums will be
10 strapped together in an arrangement of seven drums called seven-packs. A seven-pack and an
11 SWB are shown in Figure WRAC-5. Rows of containers will be placed in the rooms three
12 high. The waste will also be emplaced in the panel access entries. After a panel is filled, a
13 closure system will be constructed to isolate the waste from further operations. The closure
14 system conceptual design uses concrete.

15 A backfill consisting of magnesium oxide (MgO) will be placed over, within, and around the
16 containers of CH-TRU waste. Backfill will be emplaced in super sacks over the top of the
17 waste stack and mini sacks within and around the waste. Backfill sacks are intended to burst
18 as the room creeps closed, allowing the granular materials to be exposed to the room
19 environment. Alkaline earth oxides (such as MgO) are known to readily react with water to
20 form hydroxides. These hydroxides are free to react with carbonic acid that may form in the
21 disposal room. The reaction buffers the brine to a pH which serves to reduce the amount of
22 actinides in solution.

23 The RH-TRU waste canisters are constructed of painted carbon steel, 26 inches (66
24 centimeters) in diameter with a maximum length of 121 inches (307.3 centimeters). The
25 maximum weight of a filled canister is 8,000 pounds (3628.7 kilograms) (DOE 1991). In
26 order for personnel to handle the RH-TRU waste, the RH waste canisters must be shielded to
27 reduce radiation levels to allowable limits. The shielded facility cask is used to transport RH-
28 TRU waste to the underground. The RH-TRU waste canister will be emplaced in a disposal
29 room wall prior to CH-TRU waste emplacement in that room. The waste canister is pushed
30 out of the facility cask and into a horizontal borehole in a disposal room wall. The borehole is
31 then closed with a shield plug. The shield plug is a cylinder 29 inches (73.7 centimeters) in
32 diameter and 70 inches (177.8 centimeters) long with a wall thickness of 1.5 inches (3.8
33 centimeters). The bottom of the plug is constructed from a 5-inch (12.7-centimeter) thick
34 plate. The 3-inch (7.6-centimeter) thick top plate also has a standard waste handling pintle.
35 The total weight of the plug is approximately 4,200 pounds (1,905 kilograms). All emplaced
36 RH-TRU waste locations will be recorded.

37 ***WRAC.4.1 Repository Configuration at the Time of Closure***

38 The anticipated final configuration of the repository at the time of closure is shown in Figure
39 WRAC-6. This is the configuration that is used as input to the conceptual model developed to

1 predict repository performance. The model geometry is discussed in Chapter 6.0, Section
2 6.4.2.1 and includes 30 separate elements. Those of interest to this analysis are Regions 23 to
3 27 in Figures 6-13 and 6-14 in Chapter 6.0. These regions include the waste disposal panel
4 (Region 23), panel closures (Region 25), the panels and access drifts in the rest of the waste
5 disposal area (Region 24), the operations region (Region 26), and the experimental region at
6 the north end of the excavation (Region 27). In addition, the conceptual model described in
7 Section 6.4 of Chapter 6.0 incorporates the stratigraphic units surrounding the repository into
8 the model as discrete regions. These include the Salado Formation outside the disposal region
9 (Region 19), MB138 (Region 20), Anhydrite Layers A and B (Region 21), the disturbed rock
10 zone (Region 22) and MB139 (Region 28) (as shown in Figure 6-13 in Chapter 6.0).
11 Parameter values have been assigned to important properties (such as porosity and
12 permeability) of these various regions. Initial values and value ranges are summarized in
13 Table 6-8 in Chapter 6.0 and are detailed in Appendix PAR.

14 The LWA limits the total disposed TRU waste to 6,200,000 cubic feet (175,600 cubic meters).
15 After waste emplacement is complete, the surface structures will be decontaminated and
16 decommissioned. This will include decontaminating the surface facilities and dismantling the
17 aboveground structures. TRU waste generated by these activities will be emplaced in the
18 repository, the last waste panel will be closed, and the remaining access entries will be
19 backfilled. The four shafts will be sealed using crushed Salado salt in combination with other
20 materials such as concrete, cementitious grout, clay, and asphalt. Appendix SEAL details the
21 shaft seal design.

22 ***WRAC.4.2 Repository Condition at Time of Removal***

23 The requirement to remove the waste does not specify when or if removal would occur, only
24 that removal not be precluded. The condition of the repository is time dependent with respect
25 to salt reconsolidation and waste compaction. For the purposes of this analysis, the DOE
26 assumes that the reason for removal is the result of a discovery or insight gained by a future
27 generation and not the result of an event that necessitates removal. This is reasonable because
28 any such event that would make it necessary to remove waste would have to be cataclysmic in
29 nature (such as meteor strike or volcanic activity). Such events, if they were sufficiently likely
30 to be of concern, would be included in the assessment of the disposal system performance.
31 All such events have been screened out as unlikely as discussed in Section SCR.1 of
32 Appendix SCR. As the result of this assumption, there are no time or cost limits imposed on
33 the removal process in this analysis. Radioactive contamination within the disposal region
34 can be removed at whatever rate is necessary to safely manage occupational and public
35 exposure.

36 Additional assumptions include the following.

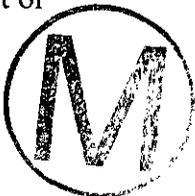

- 37 • The reason for waste removal is known and what will be done with the waste is
38 unimportant. This analysis need only demonstrate removal feasibility.

- 1 • The length of time the repository has been closed at the time of removal is known to
2 those planning the removal and the anticipated conditions of the waste panels and
3 panel closure can be determined for use in designing removal systems (see Chapter 6.0
4 and Appendix SCR for a discussion of rock creep and porosity and permeability values
5 assumed for performance assessment).
- 6 • The CH-TRU containers have been breached.
- 7 • Removal of most of the waste means that all waste within the disposal region will be
8 removed, however contamination that has migrated into marker beds and moved out of
9 the disposal region will not be removed.

10 Numerical calculations have been performed for the repository which are focused on
11 predictions of performance over 10,000 years. In the shorter term, the configuration of the
12 excavation and waste within the repository is changing as it reaches a steady state
13 configuration. As steady state is reached, the brine inflow rate is affected by the increasing
14 pressure in the repository caused by gas generation and creep closure. These three phenomena
15 are related in the numerical modeling that is detailed in Chapter 6.0. All of these phenomena
16 and the various associated states of the excavation need to be considered in evaluating the
17 feasibility of removal. In no case, however, are conditions expected to render removal
18 impossible.

19 Gas generation affects pressure within the excavation, which in turn is an important parameter
20 in creep closure. The computer simulation of this process uses an average-stoichiometry
21 model to estimate the potential for gas generation in the waste disposal region. Parameter
22 values for the average-stoichiometry gas generation model are in Section 6.4.3.3 of Chapter
23 6.0. Modeling shows that gas pressure in the disposal room can range from slightly above
24 atmospheric to near lithostatic. The model assumes that interbed fracturing occurs at high
25 pressures thereby limiting pressure buildup. If the agency removing the waste in the future
26 anticipates that high pressures are present, techniques are available to detect and safely relieve
27 such pressures. Such techniques are currently in use in the WIPP to prevent dangerous
28 pressure blowouts from localized pressurized zones ahead of mining. The technique involves
29 drilling small diameter probe holes into the rock ahead of the mining machine.

30 For the computer simulation used in this analysis, the DOE conceptualized the Salado as a
31 porous medium composed of several rock types arranged in layers, through which fluid flow
32 occurs according to Darcy's Law. This model was chosen because it can be simulated using
33 standard numerical techniques and because it is the most conservative of the three
34 mechanisms in that it predicts the maximum rate and cumulative volume of brine inflow.
35 Two rock types, impure halite and anhydrite, are used to represent the intact Salado. Near the
36 repository, the disturbed rock zone (DRZ) has increased permeability compared to intact rock
37 and offers little resistance to flow between anhydrite interbeds and the repository. Except for
38 the DRZ and anhydrite interbeds, under certain circumstances, this simulation assumes
39 spatially constant properties for Salado rock repository. The inference is that there is little

1 variation in large-scale averages of rock or flow properties across the disposal system.
2 Assumptions about Salado flow in general are presented in Section 6.4.3.2 of Chapter 6.0.
3 This model serves to maximize the potential brine inflow to the repository.

4 In the computer simulation, brine flows from the Salado and into the repository in response to
5 fluid potential gradients that form over time. Because of the low permeability of the impure
6 halite and relatively small surface area of the excavation, direct brine flow between the impure
7 halite and the repository is limited. The interbeds, however, can serve as conduits for brine
8 flow between the impure halite and the repository. Conceptually, brine flows laterally along
9 higher-permeability interbeds towards or away from the repository and vertically between the
10 interbeds and the lower-permeability halite. Because the interbeds have a very large contact
11 area with adjacent halite-rich rock, even very small flux from the halite into the interbeds (for
12 brine inflow) or to the halite from the interbeds (for brine outflow) can accumulate into a
13 significant quantity of brine.

14 Alternatively, in the modeling for the disturbed case, brine could flow into the repository as
15 the result of a drill hole that connects a disposal panel with the Castile Formation. In such a
16 case, a portion or all of the excavation could be saturated with brine. Removal feasibility
17 must consider a range of brine saturation ranging from dry to saturated.

18 Creep closure of the excavation is the focus of a computer model that implements the
19 repository processes associated with rock properties in the repository rooms and the shafts.
20 The amount of waste consolidation resulting from creep closure, and the time it takes to
21 consolidate the waste, are governed by properties of the waste (waste strength), properties of
22 the surrounding rock, the dimensions and location of the room, and the quantities and pressure
23 of fluids present in the room. Creep closure of waste disposal areas will cause their volume to
24 decrease as the Salado deforms to consolidate and encapsulate the waste, changing waste
25 porosity and permeability. Waste strength and fluid pressure may act to resist creep closure.
26 The conceptual model implementing creep closure is discussed in Section 6.4.3.1 of Chapter
27 6.0.

28 Fluids that could affect closure are (1) brine that may enter the repository from the Salado and
29 is present in the repository when it is sealed, and (2) gas produced by reactions occurring
30 during waste degradation. Closure and consolidation slowed by fluid pressure in the
31 repository can be quantified according to the principle of effective stress:

$$\sigma_T = \sigma_e + p \quad (1)$$

32
33 where σ_T is the stress caused by the weight of the overlying rock and brine (an essentially
34 constant value), p is the pressure of the repository pore fluid, and σ_e is the stress that is applied
35 to the waste skeleton or matrix. In this formulation, the waste is considered a skeleton
36 structure immersed in pore fluids. As the pore pressure increases, an increasing amount of
37 overburden stress is supported by pore fluid pressure, and less overburden stress is supported
38 by the strength of the waste matrix. Because of the strength, waste consolidation can cease

1 even if pore fluid pressures do not reach lithostatic. If gas and brine quantities in the
2 repository stabilize, creep closure will act to establish a constant pressure and void volume.

3 Creep closure becomes an important consideration for the removal process since it
4 determines, to a major extent, the dimensions of the excavation that is needed to remove the
5 waste and the condition of the rock that must be mined. Conditions where the creep has been
6 minimal also indicate the situations where brine content or gas pressure are highest and
7 represent the most hazardous conditions.

8 ***WRAC.4.3 Summary of Conditions to Be Anticipated for Removal Feasibility***

9 Based on the descriptions in the preceding sections, there are five potentially hazardous
10 conditions that must be anticipated in preparing for the removal of disposed waste. These are
11 radioactivity, hazardous constituents, gas, brine, and rock integrity.

12 The amount of radioactivity depends on the time at which removal is initiated. Within the
13 first 300 years of disposal, it may be necessary to consider treating (removing) RH-TRU and
14 CH-TRU waste differently, because of higher radioactivity. Beyond 300 years, all the waste
15 can be managed as CH-TRU waste. Regardless of when removal is initiated, the inventory of
16 the waste documentation that will be accumulated by the DOE during operations and archived
17 after closure will contain sufficient information to determine rather precisely the radioactivity
18 levels to be anticipated and the locations of any containers of waste that may pose higher
19 radioactivity hazards.

20 With regards to the hazardous constituents in the waste, the volatile organics do not occur in
21 sufficient quantities to pose a hazard as long as adequate ventilation is provided. Non-volatile
22 hazardous constituents only pose threats if they are released during the removal process.
23 Here, as with both the volatile components and the radioactive contaminants, proper
24 ventilation will be needed to provide adequate protection to workers, the public, and the
25 environment. If environmental protection laws are the same at the time of removal as they are
26 today, the planning for removal will require that the agency implementing removal provide
27 detailed plans for controlling hazardous constituent contamination.

28 Gas pressures can range from one atmosphere (14.7 pounds per square inch or 0.101
29 megapascals) to pressures near 2,000 pounds per square inch (13 megapascals). Experience
30 with mining in halite indicates that in virgin rock, high pressure zones are maintained because
31 of the low permeability of the rock. Therefore, mining activities are conducted in anticipation
32 of pressure in areas where such pressures are known to exist. Due to the nature of the disposal
33 operations and the panel closure practices, pressures could vary from panel to panel.

34 Brine quantities can vary from little to no brine, caused by brine consuming processes such as
35 corrosion and microbial degradation, to panels full of brine as the result of a borehole that
36 connects the repository with a brine pocket in the Castile Formation. As with gas, the quantity

1 of brine can be different from one panel to the next because of the anticipated efficiency of the
2 panel closures.

3 The amount of pore space in a disposal panel can be used to represent the degree of
4 consolidation that has occurred due to creep closure. While brine and gas can act to maintain
5 rather large pore volumes in a sealed panel, this condition is considered unlikely since creep
6 closure acts fairly rapidly and it is unlikely that sufficient brine and subsequent gas will be
7 available to support large pore volumes without an external source such as a Castile brine
8 pocket. Because active and passive controls are expected to deter human intrusion for up to
9 700 years after closure, an encounter with such a brine source is not expected during this time
10 period. Consequently, the repository is expected to reach its maximum closure before large
11 quantities of brine are available. In this case, the resulting pore volume is likely to be about
12 30 percent and the excavation will have closed to less than half of its original height.

13 Each of the factors above represent variable conditions that the removal planning activity
14 must evaluate prior to actually removing the waste from the repository. None of these are
15 expected to create conditions that will render the waste impossible to remove. However, the
16 safety hazards imposed by the ranges of possible conditions dictate careful evaluation and
17 appropriate planning prior to removal.

18 **WRAC.5 Sequence of Steps to Remove Waste**

19 The DOE has identified a sequence of five phases for implementing removal:

20 Phase 1 — planning and permitting.

21 Phase 2 — initial aboveground setup and shaft sinking.

22 Phase 3 — underground excavation and facility setup of underground ventilation,
23 radiation control, packaging areas, decontamination areas, maintenance,
24 remote control center, and personnel support rooms.

25 Phase 4 — waste location and removal operations, including mining waste removal,
26 packaging, package surveying and decontamination, transportation to surface,
27 staging for off-site transportation, and off-site transportation.

28 Phase 5 — closure and D&D of the facility.

29 Each of the five phases is summarized below and described in detail in Section WRAC.6.

30 **WRAC.5.1 Planning and Permitting**

31 A decision to remove waste will initiate the planning and permitting phase. Permitting
32 requirements will be based on governing regulations at the time removal is authorized. The

1 planning and permitting program will identify all permits and research the available
2 technologies at that time to determine available removal techniques and the condition of the
3 repository. After initial research is completed, a plan will be drafted to itemize and schedule
4 all removal activities. It is at this stage that initial estimates of the condition of the waste will
5 be made. These will be based on the performance assessment results, the record of
6 reassessments that may have been done as the facility was filled, the records of the waste that
7 was actually placed in the facility, and any other information that may be useful in
8 determining the status with regard to pressure, water content, and disposal room
9 configuration. Strategies for evaluating the conditions in the repository will be developed.
10 These may include surface drilling or drilling from within an initial excavation adjacent to the
11 waste areas. Appropriate geophysical techniques and other remote sensing measures will be
12 identified for determining the condition of the waste areas in a manner that minimizes the
13 chance for radiation exposure.

14 ***WRAC.5.2 Initial Aboveground Setup and Shaft Sinking***

15 Aboveground support buildings will house the exhaust fans and any radiation control
16 equipment such as HEPA filters, administration facilities, operations and maintenance
17 facilities, control center, waste staging and decontamination areas, the warehouse (containers),
18 laboratories, and others as deemed necessary. Initial estimates of the amount of mining
19 necessary will be made based on the results of the planing phase. The amount of mining will
20 dictate the size and capacity of the surface support facilities.

21 ***WRAC.5.3 Underground Excavation and Facility Setup***

22 After the shafts are completed, drifts will be run and ventilation paths will be established
23 using conventional mine ventilation techniques. During shaft sinking, provision will be made
24 to test the muck prior to its release to the surface to detect radioactive or hazardous constituent
25 contamination. If such contamination is found, shaft muck will be isolated for future
26 disposition. If contamination is minor, this material will likely be isolated from the
27 environment by placing it back into the facility at the time of closure. Underground support
28 and service areas will be excavated. The location of the shafts and initial excavations will be
29 determined based on the anticipated brine and gas conditions. These areas will have sufficient
30 intact salt between them and the waste areas that seepage or blowout of contaminated brine or
31 gas into the shafts and service areas will be precluded. There are not expected to be any
32 limitations on the amount of distance that can be specified between the wastes and the service
33 areas. Support rooms will be excavated for maintenance, control, and packaging. Air locks
34 will be constructed to provide the necessary level of ventilation control and separation
35 between contaminated and non-contaminated areas. All equipment required for removal,
36 packaging, and related support equipment will be installed.

37 Excavation will be in two stages. Initial excavation will not contact waste and will provide
38 for mine support rooms, haulage drifts, ventilation, and access to the waste. The second stage
39 will remove the waste.

1 **WRAC.5.4 Waste Location and Removal Operations**

2 The waste removal will be performed in discrete operations depending on the anticipated level
3 of radioactivity. The waste will be removed by mining the area where the waste was
4 emplaced. The mined waste will be transported to the packaging areas. The waste can be
5 removed many ways using standard equipment. Section WRAC.6.2 contains a brief
6 description and describes the feasibility of using various mining techniques for waste removal.
7 An appropriate level of radiological controls will be used depending upon the radioactivity of
8 the mined waste.

9 **WRAC.5.5 Closure and D&D of the Facility**

10 After waste is removed from the repository, the facility will be decommissioned according to
11 the current regulations at that time.

12 **WRAC.6 Removal Implementation**

13 To support the requirement that waste removal is not precluded, a system for waste removal is
14 described using available mining technologies. This description includes standard shaft
15 sinking practices and drift excavations. Standard mining techniques may be used until
16 contamination or radiation exceeding personnel safety limits then in force are encountered. In
17 these contaminated areas, currently available remote controlled mining equipment or
18 equipment modified with off-the-shelf systems may be used. Where practical or necessary,
19 removal operations will be performed remotely. All support, radiation and air quality
20 monitoring, and geotechnical surveying will be performed remotely in the contaminated areas.
21 The clean and contaminated areas will be segregated from each other and maintained using
22 separate air intake paths and ventilation control structures.

23 The excavated waste and materials will be placed in appropriately designed waste containers.
24 The container surfaces will be decontaminated if necessary prior to being transported
25 aboveground. Aboveground facilities will include a control center where any necessary
26 remote waste handling and packaging operations are coordinated, and a decontamination area
27 where waste containers will undergo any necessary additional decontamination. The waste
28 containers will be staged aboveground for transportation. A control center in the underground
29 will provide the interface between the aboveground control center and the underground
30 operational activities.

31 The mining and waste removal operations will be designed to reduce the amount of
32 contamination and exposure to allow limited human access for assessments, equipment
33 retrieval, and equipment repairs. Operations will be designed to reduce human involvement to
34 the extent practicable. Radiological work will be performed using standard industry practices
35 and approved procedures.

1 The mining operations will use standard equipment to sink the shafts and excavate the drifts
2 and support rooms. After the underground support areas are completed, the waste will be
3 removed. Smaller scale mining equipment will be used to perform the removal.
4 Modifications to the equipment will enable the vehicles and support equipment to be remotely
5 controlled and handle the waste materials. The length of time since disposal will determine
6 whether or not the RH-TRU and CH-TRU wastes will be retrieved in separate operations. It
7 is currently anticipated that the radioactivity level of RH will decay to CH levels within 300
8 years after disposal (DOE 1995). Thus if removal is conducted subsequent to 300 years after
9 disposal, a single mining operation may remove CH and RH simultaneously. However,
10 removal prior to that time may require separate operations. Because RH wastes may pose a
11 greater radiation hazard, RH-TRU removal activities may be more rigorous in order to limit
12 the exposure to personnel. RH-TRU waste should be removed as intact as possible.

13 The preamble to 40 CFR Part 191 states that waste removal must be feasible but would likely
14 incur great cost and overall occupational hazard. No time limit is specified. The removal
15 approach will include measures that reduce the overall hazards but will require a long time
16 period to complete. No time limits or cost estimates are included in this study.

17 The removal requirement states that removal of most of the waste will not be precluded but
18 does not quantify the term most. This study assumes that the quantity removed shall be the
19 amount that can be removed practically. No quantitative figure is specified because removal
20 is speculative. The amount that practically can be removed using the technologies available at
21 the time of removal shall be achieved. Since today's equipment is very effectively used to
22 mine materials deposited millions or billions of years ago, this same equipment technology
23 would provide for the feasibility to remove the waste anytime during the regulatory time
24 frame.

25 ***WRAC.6.1 Planning and Permitting (P&P)***

26 The need to remove the waste would initiate the planning and permitting phase. By definition
27 (40 CFR § 191.02[1]), waste removal does not occur until after disposal. The permitting
28 requirements will be based on governing regulations at the time removal is authorized. The
29 planning and permitting program will identify all required permits. This program will also
30 research the available technologies to determine the appropriate removal techniques, the waste
31 conditions, and the repository conditions (see Chapter 6.0 for performance assessment
32 assumed conditions after repository closure). After the initial research is completed, a plan
33 will be drafted to itemize and schedule all removal activities.

34 The following considerations would be included in the planning and permitting process for the
35 WIPP. These are necessarily general since the actual activities are solely dependent on the
36 conditions at the time removal is deemed necessary. It should be noted that technologically,
37 removal could be accomplished without any of the steps in this section. Such brute force
38 approaches would meet the requirement of describing feasible techniques for removal; they
39 are not, however, considered to be prudent.

1 **Availability of Records.** Available records will be collected to determine the location of
2 waste containers, the nature of the waste placed in the facility, the underground excavation
3 conditions during operations and at the time of closure, the location of seals and panel
4 closures, and the amount and nature of backfill materials. Since the DOE plans to place
5 records in numerous locations, records should be readily available for needed evaluations.
6 Additionally, WIPP will also have complete inventories of the contents of both the buried
7 CH and RH containers.

8 **Location of the Site.** Records and markers will be used to identify site locations such as
9 the previous shaft locations, the area of the disposal region footprint, previously drilled
10 boreholes, location of monitoring activities, and other features that will aid in delineating
11 the areas for new excavation and new surface structures.

12 **Background Environmental Conditions.** A baseline of environmental conditions will
13 be established prior to any surface disturbing activity in order to get an accurate
14 assessment of pre-operational conditions. Background measurements will be compared
15 with environmental data stored in the site archives to determine any changes in conditions
16 since the closure of the facility.

17 **Time Since Disposal.** This will be used to determine the expected condition of the
18 disposal rooms, the amount of radioactivity and hazardous constituents that need to be
19 dealt with, the amount of migration outside the disposal zone that may have occurred, and
20 the presence of potential hazardous conditions such as pressurized gas and brine.

21 **Facility Design.** Initial facility designs will be prepared so that appropriate technologies
22 can be identified and so that environmental impacts can be assessed. Release and
23 exposure pathways will be identified and risk analyses performed to ensure appropriate
24 environmental protection measures are taken. Design will be in accordance with
25 applicable commercial and regulatory standards in effect at the time. Regulations such as
26 those promulgated by the Occupational Safety and Health Administration and the Mine
27 Safety and Health Administration will be given due consideration in designing systems
28 that are protective of human health and the environment. Final facility design will be
29 appropriately reviewed and approved by the implementing agency and appropriate
30 regulatory organizations.

31 **Permitting.** Environmental regulations governing releases to environmental media and
32 protection of the public from exposure to noise, gases, dust, hazardous waste,
33 radioactivity, and other potentially harmful substance will be identified and appropriate
34 permits obtained in the time frames dictated by the regulations.

35 **Radiological Controls.** The removal process will require a comprehensive assessment of
36 the facilities and the precautions necessary to ensure the safety of workers and the public
37 during the entire removal operation from initial coring until final closure and
38 decommissioning of the facility. The facilities will include appropriate areas for washing

1 and decontamination of containers and equipment and separate areas for the
2 decontamination of personnel should such requirements arise. Decontamination areas and
3 washing areas will be designed and constructed both in the underground and on the
4 surface. Special areas will also be constructed on the surface and in the underground for
5 storage of material and/or containers having high radiation levels. Such areas will be
6 shielded to permit operational activities nearby without undue risk to personnel. Rigorous
7 radiation and hazardous material monitoring of all activities from initial borehole drilling
8 and coring to actual removal will be required until such time as removal activity
9 experience provides sufficient information to understand the actual conditions existing in
10 the repository and permit formulation of appropriate monitoring policy.

11 ***WRAC.6.2 Aboveground Setup and Shaft Sinking***

12 Existing geological characterization data will be supplemented with new borings at the site.
13 During all boring, shaft sinking, and mining activities in the vicinity of the waste panels
14 careful monitoring will be conducted to ensure early determination of the presence of any
15 hazardous or radioactive material. An initial shaft location sufficiently distant from the waste
16 will be identified and drilled. Coring in the vicinity of the repository horizon will be
17 performed in order to capture any horizons that contain radioactive contamination caused by
18 brine migration through marker beds. The level of contamination will be assessed and
19 appropriate precautions taken to protect personnel, the public, and the environment from
20 contamination. Such precautions are used today in cleanup activities in which contamination
21 is kept within well defined barriers and entrance and egress is carefully controlled and
22 monitored. Emphasis will be placed on avoiding the areas that were originally mined for the
23 repository. The DOE currently believes that for the WIPP, the best approach to the waste is
24 from the south because this area avoids the existing shafts and mined areas.

25 Use of the intact portion of the formation instead of using previous shafts and tunnels
26 minimizes the ground control problems. Additional geological studies would be conducted to
27 determine the adequacy of the rock south of the repository.

28 Aboveground support buildings will be constructed to house the exhaust fans and ventilation
29 (HEPA) filters, administration offices, engineering offices, training facilities, safety facilities,
30 maintenance support facilities, control center, waste staging and decontamination areas, and
31 warehouse. Portable and/or temporary structures such as trailers could be used for
32 miscellaneous activities. Power and water distribution network shelters will be required.

33 Where practicable, aboveground support facilities should be designed for later disassembly
34 and removal to facilitate decommissioning. Removal facilities would closely resemble those
35 currently in use at the WIPP and described in Chapter 3.0 with some additional radiological
36 control facilities and decontamination facilities.

37 A shielded area for the protection of personnel from higher levels of radiation, similar in
38 construction to the shielded storage room currently located in the Waste Handling Building

Title 40 CFR Part 191 Compliance Certification Application

1 (see Appendix D&D), may be required to handle and store the RH-TRU canisters and their
2 containers prior to off-site shipment. This area will contain all the equipment necessary to
3 transfer the RH-TRU waste into suitable waste containers and load shielded shipping casks. If
4 necessary, remote operations can be used for any removed waste that exceeds CH-TRU safe
5 handling levels.

6 Security fencing will be required around the facilities. The extent of the security devices
7 required will be governed by the regulatory requirements at that time.

8 A control center will be located aboveground that houses the personnel and equipment that
9 controls the remote mining equipment and all other remote operations.

10 At least three shafts will be constructed. The number and size of the shafts will be based on
11 removal throughput requirements, airflow requirements, and mining regulations at that time.
12 The underground ventilation requirement should be lower than the original ventilation system
13 assuming a reduction in both manpower and diesel equipment usage. To reduce the discharge
14 of hazardous and radioactive particulate contamination, the removal working area and
15 packaging areas will be provided with separate HEPA filtration systems. This precaution will
16 reduce migration of particulate material from the mining areas.

17 The three shaft concept would include two intake shafts and an exhaust shaft. The current
18 WIPP shaft designs would be adequate, although technology improvements may make
19 operations more efficient and reliable.

20 Each shaft will include a hoisting system. The waste handling shaft (WHS) and hoist will be
21 fully enclosed and will allow air intake without backflow. The WHS will be an air intake
22 shaft that ventilates the maintenance, packaging, and contaminated work areas of the mine.

23 The ventilation exhaust system for the removal of the waste will be significantly more
24 complex than the system supporting waste emplacement. Because of the likelihood of the
25 production of hazardous and radioactive particulate material during the remote removal of
26 waste material, the ventilation system will require local systems within the underground that
27 include the appropriate exhaust fans, monitoring, and HEPA filtration systems used to filter
28 the exhaust air during removal operations. The levels of dust in a potentially highly
29 contaminated environment will present a significant maintenance challenge. Maintenance of
30 these systems will require high degrees of redundancy of system components, system
31 configurations, or flow paths. Flexibility of operation will be a major operational requirement
32 of the ventilation system design in order to ensure that removal operations remain within the
33 regulatory and safety limitations imposed for workers and the general public. The system
34 design must permit remaining within the allowable limits at all times. Since the potential for
35 hazardous or radioactive material contamination will exist, once waste removal begins,
36 filtration of all exhaust air will be required. Self-cleaning or roughing pre-filters may be used
37 to increase HEPA filter life and reduce down time for filter change-out.

1 After the first shaft (no particular order) is completed, the others may be excavated from the
2 bottom up using a drill and ream system similar to the system used at WIPP to excavate the
3 existing air intake shaft. This will require access entries (drifts) to be excavated to the base of
4 each shaft and drilling to this area. An ore transfer station will also be installed to facilitate
5 removal of excavated salt (uncontaminated) from drift and support area mining.

6 **WRAC.6.3 Underground Excavation and Facility Setup**

7 After the shafts are completed, drifts will be excavated using commercially available
8 equipment such as continuous miners, roadheaders, scalers, and ventilation paths will be
9 established using air control regulators. Support rooms for use as maintenance areas, control
10 rooms, and packaging areas will be excavated. Air locks will be constructed to isolate the
11 clean areas from the contaminated areas by use of differential pressure. All equipment
12 required for removal, packaging, and related support activities will be installed.

13 Excavation will be in two phases. The initial excavation will not contact waste but will mine
14 support rooms and haulage drifts that provide ventilation and access to the waste panels. A
15 barrier pillar will be maintained. The size of the barrier pillar depends on the anticipated
16 conditions in the waste panels. The barrier pillar will provide protection from blowout or
17 flooding due to pressurized gas or brine. The second phase will remove the waste.
18 Conceptual layout of removal operations is shown in Figure WRAC-7.

19 Air locks will be used to allow travel between air circuits while maintaining the isolation of
20 contaminated areas from the clean areas. Lined sumps may be used to manage liquids if
21 conditions involving flowing brine are encountered.

22 The following support areas may be required:

23 **Control Centers.** Rooms that contain the remote control support interface between the
24 surface control center and the equipment supporting the underground ventilation, mining,
25 packaging, and transportation operations.

26 **Maintenance Rooms.** Shop areas where all maintenance and repairs are performed,
27 including wash bay and parts warehouse for support equipment.

28 **Personnel Support.** Lunch room, lockers, washrooms, and facilities.

29 **Container Warehouse.** Storage for clean, empty waste containers, and decontamination
30 supplies.

31 **Packaging Area.** Waste emplacement into containers, container filling, and container
32 sealing area.

33 **Decontamination Area.** Container radiation survey and decontamination area.

2 **Container Staging Area.** Lower hoist loading area with staging area (clean area) located
3 in clean intake air feeding contamination area; final radiation survey area.

4 ***WRAC.6.4 Waste Location and Removal Operations***

5 A single drift should be excavated around the waste panels. This drift will provide ventilation
6 that will be used during removal operations. After the support, ventilation, and access drifts
7 are completed, the first panel can be entered to remove the waste. Panel 9, the panel closest to
8 the exhaust shaft should be excavated first to reduce initial contamination. An entrance and
9 exit will be excavated, dust and moisture control systems installed, and isolation bulkheads
10 erected. The location of the panel closures should be available from the detailed information
11 at record centers and archives. With the exception of mining Panel 9 (the southern most
12 portion of the access drifts) the panel closures can be used as markers for locating panels and
13 drifts. To determine the relative position of the waste, ground penetrating impulse radar
14 technology could be used. Impulse radar technology, specifically a Geophysical Survey
15 Systems, Inc. (GSSI) SIR-7 impulse radar, has been successfully tested in salt mines and has
16 demonstrated the capability of locating metallic targets up to ten meters away (Cook 1982).
17 The access entries could be completed and the entrances to each panel could be located by the
18 panel closure systems and radar. Radar and gamma detectors could be used to help locate the
19 RH-TRU waste. The gamma detectors should be effective during the first few hundred years
20 after disposal prior to extensive decay of the RH radioactivity.

21 Initially, each waste panel will be evaluated using a small diameter probe hole drilled from the
22 access drifts. The hole will be used to investigate the conditions within the panel. Of
23 particular interest will be the porosity (degree of consolidation), pressure, and moisture
24 content. In addition, gasses will be tested for explosive or flammable constituents.

25 For conditions requiring that the CH-TRU and RH-TRU waste removal operations be
26 performed in separate operations, the CH-TRU waste will be removed by mining the area
27 where this waste was emplaced. The CH-TRU waste and surrounding rock will be removed
28 and transported to the packaging areas without disturbing the RH-TRU waste. The RH-TRU
29 waste will be removed by excavating the rock salt around the waste and removing it in as
30 intact a condition as possible. This waste may be placed in a waste container at the work face
31 and then transported to the packaging area. The waste container may be the shipping
32 container if sealing and decontamination are possible underground or it may be over-packed at
33 the packaging area prior to decontamination.

34 The CH-TRU waste can be removed many ways using standard equipment. The waste could
35 be mined out using a large-scale continuous miner. Continuous miners such as the EIMCO
36 Coal Machinery Division's 3612 Marietta Drum Miner (see Figure WRAC-8) have been used
37 very successfully at WIPP and are readily available. However, this method does have the
38 potential to spread excessive amounts of particulate contamination and could be difficult to

Title 40 CFR Part 191 Compliance Certification Application

1 control particularly with respect to the RH-TRU wastes. A more practical approach would be
2 to use small-scale mining equipment such as road headers, scalers, hydraulic breakers, small
3 loaders, and excavators. A small head continuous miner or a roadheader (telescopic boom
4 miner) similar to a Hawker Siddley DOSCO M.D. 1100 (see Figure WRAC-9) could be used
5 to excavate a large portion of the waste. The other extraction equipment would be used to
6 remove the most difficult waste such as large metallic items.

7 A practical approach to CH-TRU removal is to excavate an area approximately three feet high
8 directly below the waste and then, using a hydraulic breaker/scaler system similar to the
9 Fletcher Model SV-4D diesel powered scaler capable of being equipped with either an Alpine
10 No Gap cutting head, a percussion scaling hammer, or a scaling claw attachment devices (see
11 Figure WRAC-10) to dislodge the waste above. Similar scaling devices have been
12 successfully utilized at WIPP and other mines in the Delaware Basin.

13 The CH-TRU waste will be excavated behind bulkheads separating the mining area from
14 normal ventilation. After removing a predetermined amount of excavated materials, loaders
15 will transport the waste materials to the packaging area.

16 The CH-TRU waste will be transferred to the waste handling and packaging system which
17 packages the waste into containers. Bulk material handling equipment may be used to transfer
18 the waste from the loaders to the waste containers. The container will move into the
19 decontamination area where it is automatically surveyed and decontaminated. The container
20 is then moved into the hoist underground staging area where it is surveyed again and
21 transported to the surface. The container will be warehoused until transported off site.

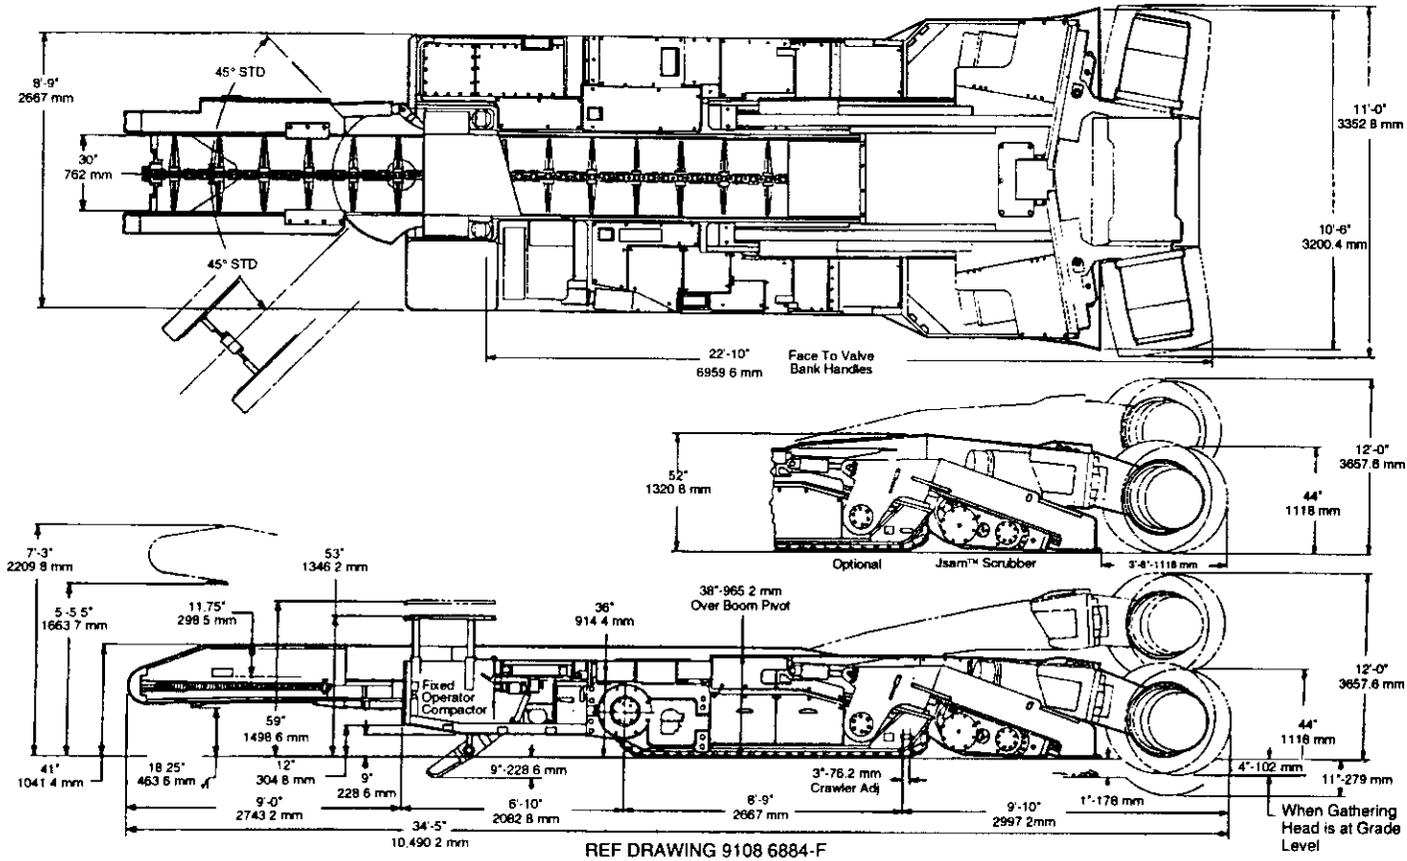

22 The CH-TRU waste containers will be selected using the regulatory requirements at that time.
23 Currently available containers will be researched to determine their suitability, and if none are
24 found, new containers will be built and certified.

25 An aboveground decontamination area will be used if any contamination is found during the
26 off-site container loading and transportation operations.

27 RH-TRU waste will be removed after the CH-TRU waste is excavated past the shield plugs to
28 allow equipment access. The equipment will be set up to remove and excavate the materials
29 around the waste. The waste will be loaded into a container and moved to the packaging area.

30 There, the container may be decontaminated, if possible, or overpacked prior to shipment
31 aboveground. After completion of any necessary decontamination, the RH-TRU waste will be
32 transported to the surface and then warehoused in a shielded area prior to off-site shipping.
33 Radiation surveying and decontamination procedures will be similar to the CH-TRU
34 operations.

35 The waste will be removed from the panel and its original access entries. After initial panel
36 waste removal is completed, all other panels will be excavated.

THIS PAGE INTENTIONALLY LEFT BLANK

1 If the removal of waste is not initiated until hundreds of years after disposal and the RH
2 radioactivity has decayed to near the activity levels of the CH waste, the decision may be
3 made to remove the RH waste in conjunction with CH waste removal. Under these
4 conditions, evaluation of the probable condition of the RH containers should be made. The
5 heavier wall thickness of the RH containers may provide an opportunity to remove the RH
6 waste intact provided that corrosion has not yet destroyed the containers' integrity. Under
7 these conditions, RH removal should be conducted in a manner similar to that described
8 above. That is, CH removal within a given panel should proceed until sufficient clearance is
9 obtained to permit installation of equipment to excavate the rock salt around the RH container
10 and then remove the container in as intact a condition as possible. Under conditions which
11 the RH container has lost its integrity, removal of RH waste would be accomplished using the
12 procedures applicable to CH waste removal.

13 ***WRAC.6.5 Closure***

14 After the waste is removed from the repository, the facility will be decommissioned in
15 accordance with the regulatory requirements applicable at that time. Closure may include
16 partial backfilling of the mine and support areas. The mine may be used for disposal of both
17 contaminated and uncontaminated muck. The shafts will be sealed (see Appendix SEAL for
18 the details of what a seal may look like) and the surface facilities will be decontaminated and
19 decommissioned (see Appendix D&D for an outline of a decontamination and
20 decommissioning program). All decontamination wastes could be packaged and shipped in
21 the same fashion as the removed waste.

22 **WRAC.7 Currently Available Removal Technologies**

23 As part of the feasibility demonstration, the DOE has identified technologies that are available
24 today that could be used to facilitate removal. These are divided into mining technologies
25 (Section WRAC.7.1) and remote removal technologies (Section WRAC.7.2).

26 ***WRAC.7.1 Mining Techniques for Waste Removal***

27 Waste removal can be accomplished in many ways using available technologies. Mining
28 techniques are the most plausible since they must be used initially to provide access to and
29 locate the waste. Methods used to extract salt and potash were briefly evaluated to determine
30 the best removal technique. Since the waste is hazardous and radioactive, the technique used
31 must limit the spread of contamination to the environment and exposure to facility personnel.
32 The condition of the waste at the time of removal will be unknown and is related to the
33 amount of time the waste was exposed to repository conditions.

34 Removal processes should be performed with as little direct human interaction as possible.
35 Limited contamination is acceptable provided that the exhaust from these areas is controlled
36 and filtered. Roughing filters and HEPA filters can be used to control contamination.
37 Limiting the air throughput in the work areas will minimize the spread of contamination.

1 Mining techniques that were evaluated include the following:

- 2 • continuous mining,
- 3 • drill and blast,
- 4 • solution mining and mechanical extraction, and
- 5 • mechanical excavation techniques.

6 **WRAC.7.1.1 Continuous Mining**

7 Continuous mining was used to excavate most of the WIPP facility. A continuous miner (see
8 Figure WRAC-8) is used to mechanically excavate materials by ripping, milling, or boring the
9 rock from the work face. Rotary drums and heads with cutting bits attached to the surface cut
10 the rock. The miner mechanically removes the loose material and transports it away from the
11 face onto a conveyor where it can be transferred to haulage equipment or transported by
12 belting to other areas. Continuous mining equipment can precisely remove rock and hold
13 tolerances in the order of a few inches. The equipment is available in a wide variety of styles
14 and sizes. Remote controlled continuous miners are commercially available.

15 The waste contains some metallic items (for example, cadmium, lead, silver) and the
16 containers are steel. Continuous mining heads can be made with bits utilizing various steel
17 alloys. Examples of these alloys include high-strength low alloy (HSLA) ordnance-grade
18 steels such as AISI 4140 chromium molybdenum steel and AISI 8650 nickel chromium
19 molybdenum steels; molybdenum or tungsten-based high speed tool steels such as M2 or T6;
20 and the powder-metallurgy-produced sintered tungsten carbide steel groups such as the six
21 percent cobalt group 2 alloy. All of these alloys are frequently used for various mining,
22 petroleum production drilling, ordnance, and tooling applications such as drilling, mining, and
23 cutting through metals, ores, and hardened rock. The equipment may be further modified by
24 changing the cutting head configuration and sizing to efficiently handle the metallic
25 substances by altering the cutting surface, speed, and bit angles. The need to address cutting
26 through metals, particularly the metal containers, will be dependent upon the time after
27 disposal that removal is initiated (see Chapter 6.0 for performance assessment assumptions
28 regarding metal persistence).

29 Large-scale continuous mining of the waste is possible but is impractical because of the
30 potential for spreading contaminated material. Excessive amounts of dust are generated
31 during continuous mining. Water is generally used for dust control which may increase the
32 spread of contamination. Water will transport the contamination into the fractures of the
33 surrounding rock.

34 Small-scale continuous mining of the waste is practical if electric equipment is used and the
35 area is isolated during mining operations. To control contamination, bulkheads can be placed
36 close to the mining face that isolates the mining activities from normal mine ventilation.
37 Ventilation in the mining area can be reduced or eliminated since remote controlled electrical
38 equipment would be used and no diesel equipment or personnel are required. Suspended

1 particles can be effectively removed from the air during mining and loading operations using
2 local HEPA filtered systems with prefiltering capability to reduce the maintenance of HEPA
3 filters.

4 WRAC.7.1.2 Drill and Blast

5 This method excavates by drilling holes in a rock face and filling the holes with explosives.
6 The explosion fractures and loosens the rock material. Other equipment is then used to
7 remove the debris and the cycle starts again.

8 This method could also be used to remove the waste. However, this method generally
9 requires personnel to drill and load and would be difficult to perform remotely. The dust and
10 fumes caused after the explosives are detonated must be ventilated and would cause a
11 contamination problem. Isolating the working areas with bulkheads would be difficult
12 because of the large pressures produced by the blast. Thus, while this method could possibly
13 be used to remove the waste, the associated problems of personnel in the vicinity, ventilation,
14 contamination, and blast side-effects make this method impractical.

15 WRAC.7.1.3 Solution Mining

16 Solution mining uses a solvent to extract the material of interest. In salt solution mining, water
17 is injected into the formation and saturated brine is pumped out.

18 A modified version of this technique could possibly be used to remove the salt from around
19 the waste at the repository level. After the salt is removed, remote controlled mechanical
20 equipment would remove the exposed waste. Hence, both standard mechanical mining
21 methods and solution mining would be required. However, this method would require large
22 amounts of water and would require a system to be designed to recycle the water. Water
23 treatment would also be required to extract salt and any contaminated material. These
24 processes involved add significant complexity to the system and the salt, and probably the
25 water, would still be contaminated and would have to be packaged along with the waste.
26 Additionally, this method would produce a large volume of contaminated material and would
27 spread contaminants into the fractures of the surrounding rock. Therefore, based on the
28 problems of the systems' complexity and of the likely ineffectiveness of those systems, in
29 general, this method is impracticable.

30 WRAC.7.1.4 Small-Scale Mechanical Excavation Techniques

31 Smaller-scale mechanical excavation techniques can be used and are the most favorable. One
32 method uses roadheaders, hydraulic breakers, and scalers (see Figures WRAC-9 and WRAC-
33 10) to dislodge material from the face by scaling or cleaving the material. This method is
34 extremely slow and precise. It produces the least amount of dust and can be performed
35 remotely.

1 Additionally, other forms of mechanical excavation equipment such as Melroe bobcats with
2 various small backhoes, manipulators, and earth moving and cutting attachments (see Figures
3 WRAC-11, WRAC-12, and WRAC-13) exist and would also be used to dislodge, move, cut,
4 and crush the waste. These types of equipment will be required to support any method used.

5 **WRAC.7.1.5 Remote Mining**

6 Two examples of remote mining operations include work in Australia and France. Australia
7 removed 198,334 tons of coal from a McQueen Company mine using a remote controlled
8 flexible conveyor train, a continuous miner, and roof-bolting machines between 1985 and
9 1987 (McQueen 1988). The French have been actively pursuing remote coal mining since
10 1972. In 1983, 93 percent of French coal shearers were remotely controlled and monitored.
11 (Boutonnat 1986)

12 In 1986, the U.S. Bureau of Mines initiated research to develop technology to enable the
13 relocation of workers from hazardous areas (Schnakenberg 1993). Such work includes
14 developing computer assisted operation of continuous miners, roof bolters, and haulage
15 systems (Schnakenberg 1993). Remote mining technology is continuing to progress making
16 the likelihood of its success in any future removal operations highly probable.

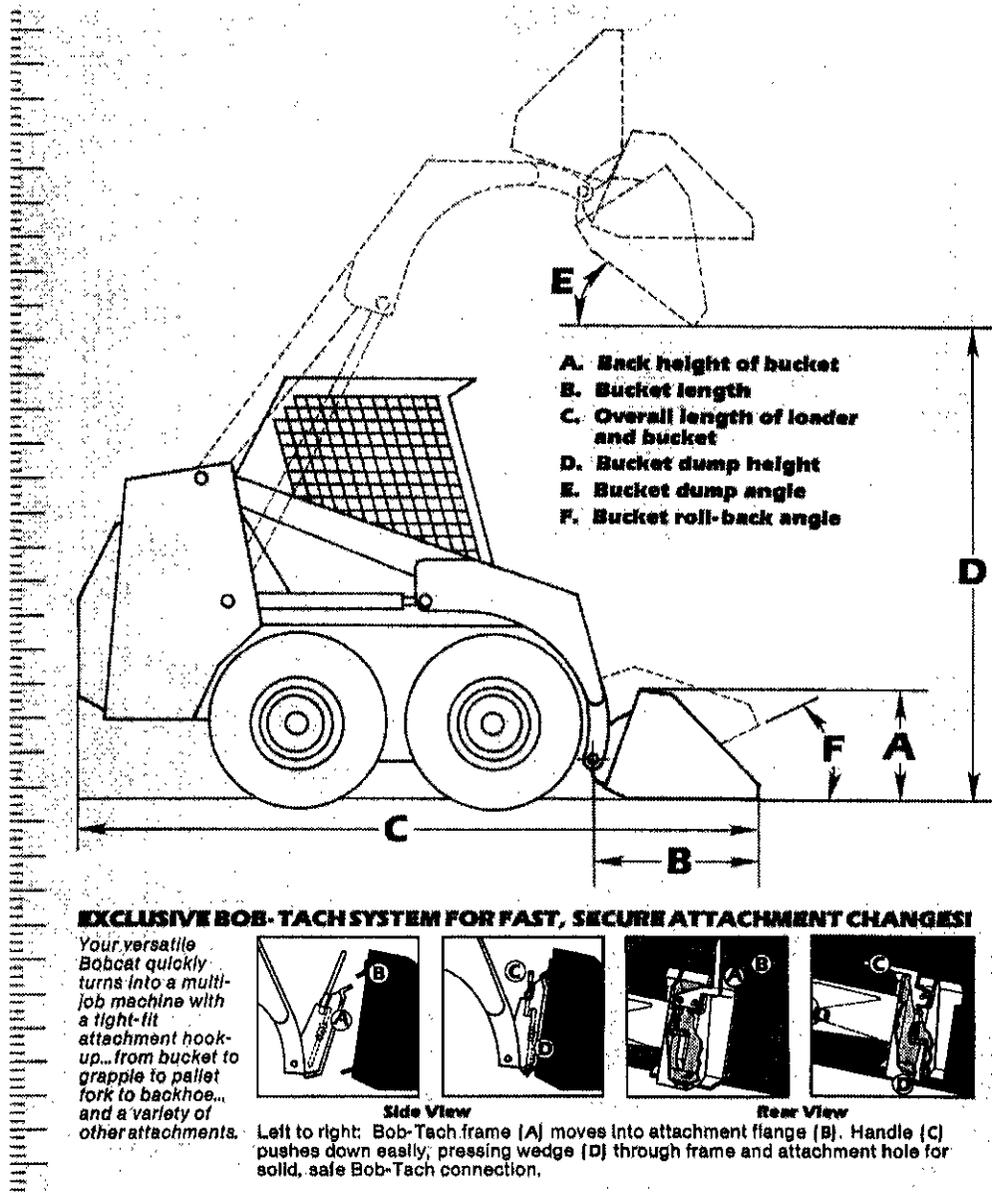

17 **WRAC.7.2 *Remote Removal***

18 On April 27, 1992, a retrieval demonstration took place that successfully retrieved SWBs
19 from a WIPP storage room. This demonstration simulated a cave-in or roof fall condition
20 with salt and metal roof support materials piled on top of the SWBs. All retrieval operations
21 were performed using remote controlled equipment.

22 The equipment used for this demonstration consisted of two remote controlled Melroe bobcats
23 (see Figures WRAC-11 thru WRAC-16), a remote controlled freestanding portable television
24 camera, a WILD TM 3000 automatic laser survey station, a portable beta-gamma radiation
25 detector, and an ANDROS Mark VA hazardous duty robot (see Figure WRAC-17). One
26 remote-controlled bobcat used a backhoe attachment and the other used either a manipulator,
27 front loader bucket, hydraulic breaker, or grapple bucket attachment. The attachments were
28 changed out when required. The equipment used both radio and tethered cable remote control
29 methods.

30 The demonstration used the robot to survey the areas using television cameras and laser
31 ranging equipment. The condition and location of the SWBs were determined using the
32 robot's data. The robot also set up equipment and surveyed the areas for radioactive
33 contamination.

34 In order to remove the SWBs, the salt and metal materials were removed and boxed in
35 containers using the remote controlled equipment. The SWBs were successfully removed
36 from the room.

Figure WRAC-11. Melroe Schematic Drawing

THIS PAGE INTENTIONALLY LEFT BLANK

FOR 700, 800 AND 900 SERIES AND ARTICULATED 1600, 2400 MTC LOADERS

INDUSTRIAL FORK GRAPPLE

Handle scrap and assorted metal. Bobcat fork grapples join the other Bob-Tech attachments that allow change ability from the operators cab. The Fork grapple is perfect for handling sharp, irregular-shaped metal, other assorted scrap and heavy duty agricultural applications.

AN ALLIED ATTACHMENT FOR BOBCAT 740s, 843, 900 AND ARTICULATED 1600, 2400 MTC LOADERS

LONGWOOD GRAPPLE

Turn your Bobcat into a high performance log handler. The Multitek Longwood Grapples* are made of high quality steel providing strength and durability for rough working conditions.

SPECIFIC APPLICATIONS FOR WHICH PRESURE A 10 INCH LIFTING HEIGHT FLUID WITH 14 INCH TOP AND FRONT WINDSHIELD BRACKETS BE USED WHEN OPERATING THE BOBCAT INCLINED AT AN ANGLE OF 30 DEGREES.

FOR BOBCAT 443, 500, 600, 700, 800, 900 SERIES, AND ARTICULATED 2400 MTC LOADERS

HYDRAULIC BREAKER

Break up concrete quick and easy.*

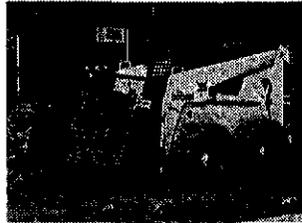

- Up To 750 Ft.-Lb. Impact energy class.
- Backhoe or Loader Mounting.
- 2-position Loader Mounting Frame for Vertical and Horizontal Breaking.
- Quick-Change Tool System - Variety of Tools Available.
- Low Recoil Operating Cycle.

*SPECIAL APPLICATIONS FOR WHICH PRESURE A 10 INCH LIFTING HEIGHT FLUID WITH 14 INCH TOP AND FRONT WINDSHIELD BRACKETS BE USED WHEN OPERATING THE BOBCAT INCLINED AT AN ANGLE OF 30 DEGREES.

FOR BOBCAT 500, 600, 700, 800 AND 900 SERIES AND ARTICULATED 1600, 2400 MTC LOADERS

PALLET FORK

Move bulky or bagged materials in one load. Hook on a Bobcat pallet fork and move your bagged or bulk material fast. Ideal for all kinds of farm chores and fertilizer handling. In industrial plants and landscaping, handle baled or pallet materials

FOR BOBCAT 600, 700, 800 AND ARTICULATED 1600, 2400 MTC LOADERS

LANDSCAPE RAKE

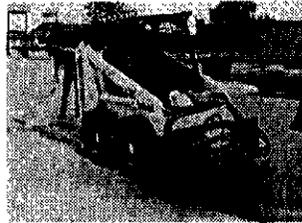

Grade, level and scarify in close quarters. Break up lumpy soil, pick up rocks as small as 3/4", grade, level and scarify in close quarters with the Bobcat Landscape Rake. Use it for ground preparation, for seeding, sodding and lawn leveling. Pick up rocks or hard-packed clumps of soil and dump them where you need them with the Bobcat Landscape Rake.

FOR BOBCAT 843 SERIES LOADERS

PLANER

Cut and remove deteriorated asphalt. The Bobcat 843 becomes an effective, cost-efficient planing machine* with the Melroe Planer attachment. Quickly removes deteriorated asphalt surfaces. An ideal tool for busy municipal and construction contractors.

*The 843 loader must be equipped with the High Torquepower Auxiliary Hydraulics option which provides 22.3 GPM and 3000 PSI for attachment operation.

THIS PAGE INTENTIONALLY LEFT BLANK

<p>AN ALLIED ATTACHMENT FOR BOBCAT 500, 600, 700, 800 SERIES & ARTICULATED 1600, 2400 MTC LOADERS</p> <h3>GANNON LANDSCAPER</h3>  <p>Grade, Scarify, backfill or level. With this tool, a Bobcat operator can grade, scarify, backfill or level in close quarters. Use it on road construction, lawn leveling, ripping hard packed soil or gravel, piling and leveling dirt, manure or other materials. Drag a load or doze it right where you need it.</p> 	<p>FOR BOBCAT 740, 840, 943 SERIES AND ARTICULATED 1600, 2400 MTC LOADERS</p> <h3>COMBINATION BUCKET</h3>  <p>Perform a wide variety of job functions. The versatile Melroe Bobcat combination bucket is ideal for coring, grappling, evening, digging, loading and dumping. And built durable with heavy-duty cutting edges and cylinders for long life on those construction, demolition, landscaping or municipal jobs.</p> 	<p>FOR BOBCAT ARTICULATED 2400 MTC LOADERS</p> <h3>COUNTERWEIGHT</h3>  <p>Now you can even lift more. With the addition of the optional counterweight attachment, you can increase the rated operating capacity of your MTC from 2400 pounds to 3000 pounds.</p> 
<p>FOR BOBCAT 500, 600, 700, 800 SERIES AND ARTICULATED 1600, 2400 MTC LOADERS</p> <h3>EARTH AUGER</h3>  <p>Dig 6"-24" holes with speed and plumb-line accuracy. Utilizing Bobcat loader hydraulics, the heavy-duty hydraulic auger bites in with low speed, high torque power. Because of a unique knuckle-joint design, the auger will dig vertical holes even though the Bobcat is working on uneven terrain.</p> 	<p>FOR BOBCAT 740, 840 AND ARTICULATED 1600 LOADERS</p> <h3>GRADER</h3>  <p>Turn your Bobcat into a high performance grading machine. Designed for use by landscaping, asphalt, curb and gutter and concrete flatwork contractors. Featuring a seven foot, six-way hydraulically controlled moldboard, operated with switches mounted on the loader's steering levers for precise control.</p> 	<p>FOR BOBCAT 760, 860, 900 SERIES AND ARTICULATED 1600, 2400 MTC LOADERS</p> <h3>GRAPPLE BUCKET</h3>  <p>Clamp onto heavy and odd-shaped objects, and move them with ease. The Bobcat industry's Grapple is the ideal attachment for handling scrap, waste or pipe. It's built strong for tough working conditions.</p>

ANDROS

ANDROS is an all-terrain, multi-tracked, remote controlled vehicle specially designed for use in hostile environments. Assigned to police or military agencies it is adept at bomb disposal and invaluable in hostage and terrorist situations. A lengthy list of options allows each unit to be customized for specific tasks including: Lifesaving, fire-fighting, ordnance deployment, and others.

REMOTEC® takes the "life" out of life-threatening situations.

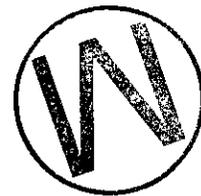

Call or Fax for additional information.

THIS PAGE INTENTIONALLY LEFT BLANK

1 Although the retrieval demonstration was performed on a small scale, it proved that remote
2 controlled equipment could be used to remove salt and metal materials from around a waste
3 container, package the excess material, and remove the waste container. The removal of
4 waste from a consolidated salt condition will involve a more complex set of circumstances.
5 However, current technological capabilities permit remote operation of current equipment and
6 will permit these complexities to be solved operationally. Thus, no new technology will be
7 required.

8 Current technology exists and is in operation in mines throughout the world to excavate
9 materials using remote controlled machinery. Remote coal mining has been performed for
10 many years by countries including Australia, France, Austria, Canada, Russia, and the United
11 States. Remote controlled continuous miners, rock bolters, drills, haulage, road headers,
12 loaders, and locomotives are examples of the equipment used at these mines (Naunkovic
13 1986).

14 **WRAC.8 Conclusion**

15 The requirement for waste removal after closure originates in 40 CFR § 191.14(f).
16 Specifically, 40 CFR § 191.14(f) states that WIPP disposal systems will be selected so that
17 removal of the waste is not precluded for a reasonable period of time after disposal (EPA
18 1993). Removal of the waste after the repository is sealed is possible. Because access to the
19 repository was accomplished using standard mining practices, access to the waste after closure
20 can be accomplished using the same mining technologies supplemented by a more extensive
21 use of remote controlled and robotic equipment. The degree of robotic and remote controlled
22 technology required to successfully remove the waste is not only available and but also has
23 been used in mining and industrial packaging activities around the world. The accessibility
24 for waste removal has no operational time limit assuming use of today's technology. 40 CFR
25 § 194.46 states that the analysis of the technological feasibility of removing the waste use
26 "...technology levels at the time a compliance application is prepared." Locating and
27 removing the waste is feasible using currently available equipment modified to operate
28 remotely. Packaging the removed waste and decontaminating the containers can be safely
29 accomplished by using established techniques. The concept of sealing and decommissioning
30 the facility will have been demonstrated prior to waste removal.

31 As stated in the preamble to 40 CFR Part 191, with respect to the waste removal requirement:

32 Any current concept for mined geologic repository meets this requirement without any
33 additional procedures or design features. For example, there is no intent to require that the
34 repository shafts be kept open to allow future recovery. To meet this assurance requirement, it
35 only need be technically feasible (assuming current technology levels) to be able to mine the
36 sealed repository and recover the waste - albeit at substantial cost and occupational risk.

37 The WIPP is a mined geologic repository and, as such, meets the removal requirement without
38 any additional design requirements since current technology can be used to remove the waste
39 if the need arises. Examples of the necessary mining equipment are in existence today, are

Title 40 CFR Part 191 Compliance Certification Application

1 readily available, and have been effectively used for mining applications. Thus, it is logical to
2 conclude that since the necessary equipment not only exists in off the shelf forms but also has
3 been effectively used in a variety of mining applications, then waste removal utilizing this
4 equipment is feasible. Partial proof of this concept has already been demonstrated by
5 retrieving waste containers from under salt and metal roof support materials using remote
6 controlled equipment.
